

Intro to Kubernetes

Kubernetes Services Overview

Kubernetes Service Objects: Microservices

Services provide abstraction between layers of an application

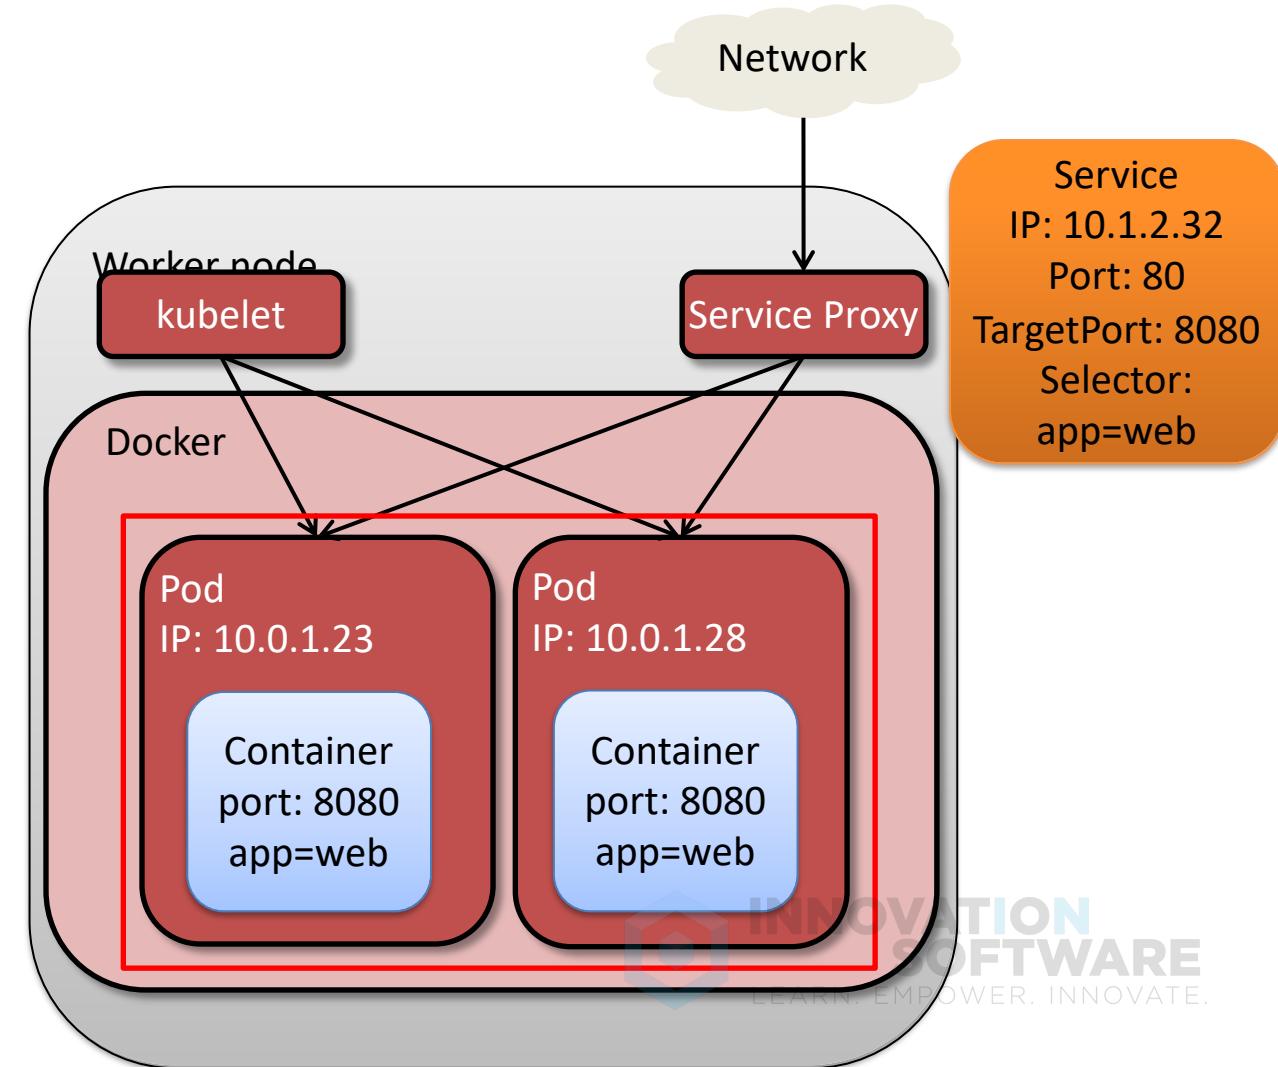

- **Service** object provides a stable IP for a collection of Pods
- Services use a label **selector** to target a specific set of pods as endpoints to receive proxied traffic
- Clients can reliably connect via the service IP and port(s), even as individual endpoint pods are dynamically created & destroyed
- Can model other types of backends using services without selectors

```
apiVersion: v1
kind: Service
metadata:
  name: wordpress
  labels:
    app: wordpress
spec:
  ports:
    - port: 80
      targetPort: 8080
  selector:
    app: wordpress
    tier: frontend
  type: LoadBalancer
```

sampleservice.yaml

Services Provide Abstraction Layer for Applications

- Services can be used for communications between application tiers
- Services can also be used to expose applications outside the K8s cluster
- Services distribute requests over the set of Pods matching the service's selector
 - Service functions as TCP and UDP proxy for traffic to Pods
 - Service maps its defined ports to listening ports on Pod endpoints

Defining a Service Using a Manifest File

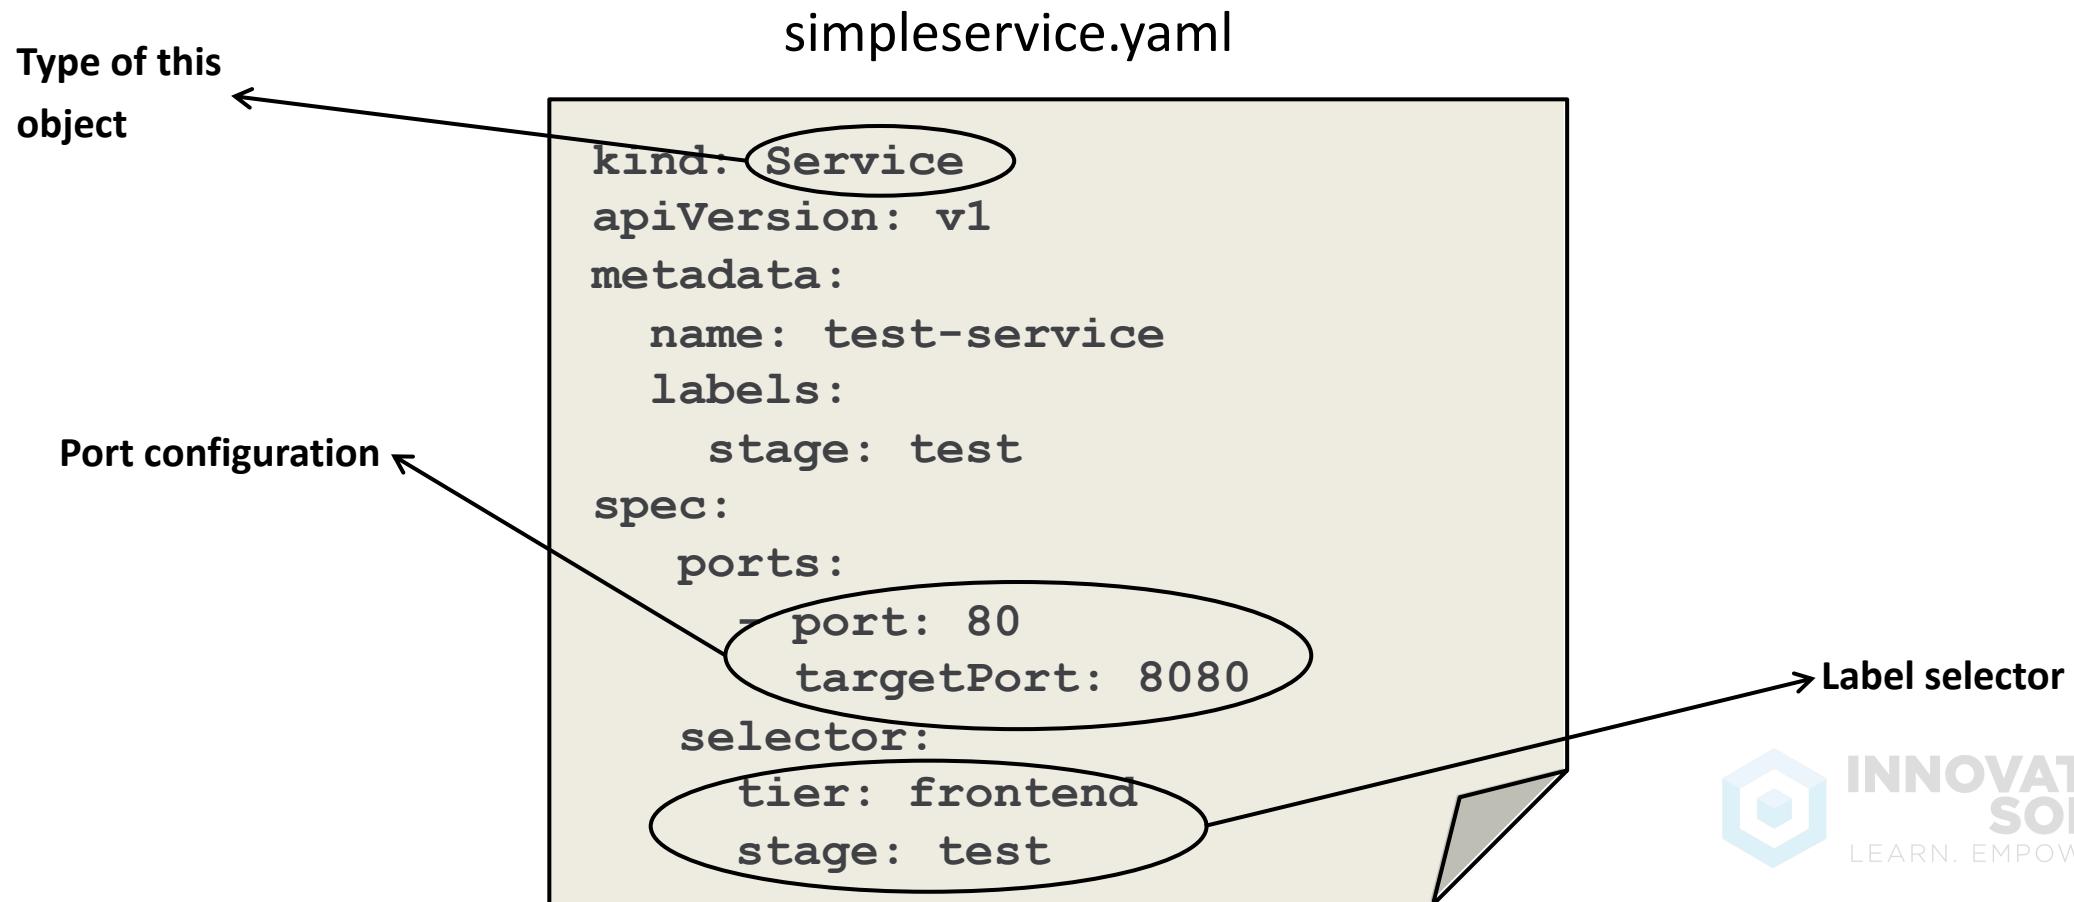

Services can be defined in YAML or JSON, like other K8s resources

- **kind** field value is 'Service'
- **metadata** includes
 - **name** to assign to Service
- **spec** includes the ports associated with the Service
 - **port** is the Service's port value
 - **targetPort** is connection port on selected pods (default: **port** value)
- **selector** specifies a set of label KV pairs to identify the endpoint pods for the Service

```
kind: Service
apiVersion: v1
metadata:
  name: test-service
  labels:
    stage: test
spec:
  ports:
    - port: 80
      targetPort: 8080
  selector:
    tier: frontend
    stage: test
```

Reviewing a Service Manifest File

ServiceTypes and Exposing Applications

- By default, a Service is assigned a cluster-internal IP – good for back-ends
 - **ServiceType ClusterIP**
- To make a front-end Service accessible outside the cluster, there are other ServiceTypes available
 - **ServiceType NodePort** exposes Service on each Node's IP on a static port
 - **ServiceType LoadBalancer** exposes the Service externally using cloud provider's load balancer
- Can also use a Service to expose an external resource via **ServiceType ExternalName**

```
kind: Service
apiVersion: v1
metadata:
  name: test-service
  labels:
    stage: test
spec:
  ports:
    - port: 80
      targetPort: 8080
      nodePort: 30080
  selector:
    tier: frontend
  type: NodePort
```

Exposing Services at L7 through Ingresses

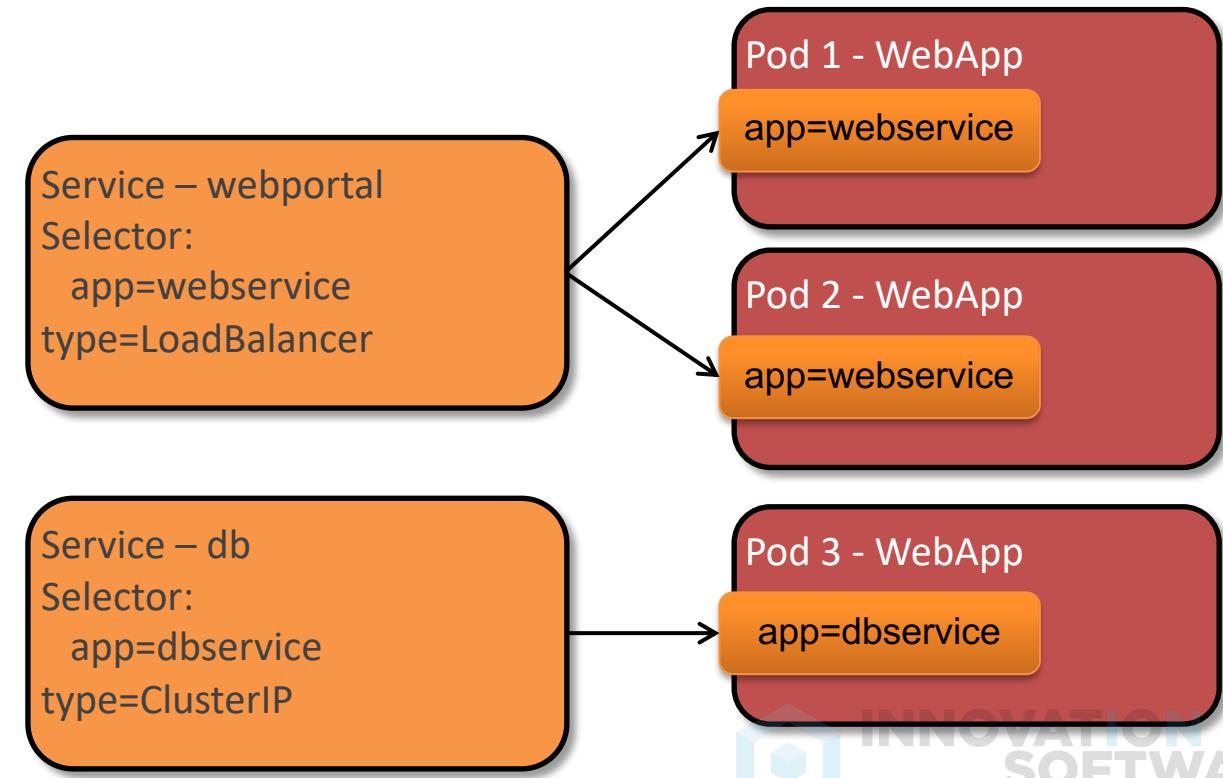

- Kubernetes also provides the facility to define **Ingress** resource to configure an external loadbalancer at L7
- Spec of Ingress resource is a set of rules matching HTTP host/url paths to specific Service backends
- Ingresses require the cluster to be running an appropriately configured Ingress controller to function (e.g. nginx)
- Useful for implementing fanout, Service backends for virtual hosts, etc.

```
apiVersion: extensions/v1beta1
kind: Ingress
metadata:
  name: test-ingress
spec:
  rules:
  - host: bar.foo.com
    http:
      paths:
      - path: /first
        backend:
          serviceName:
            firstservice
            servicePort: 80
      - path: /second
        backend:
          serviceName:
            secondservice
            servicePort: 80
```

Selecting Pods as Service Endpoints

Service's pod selector based on labels

- Multiple pods can have the same label, unlike pod names which are unique in the namespace
- K8s system re-evaluates Service's selector continuously
- K8s maintains **endpoints** object of same name with list of pod IP:port's matching Service's selector

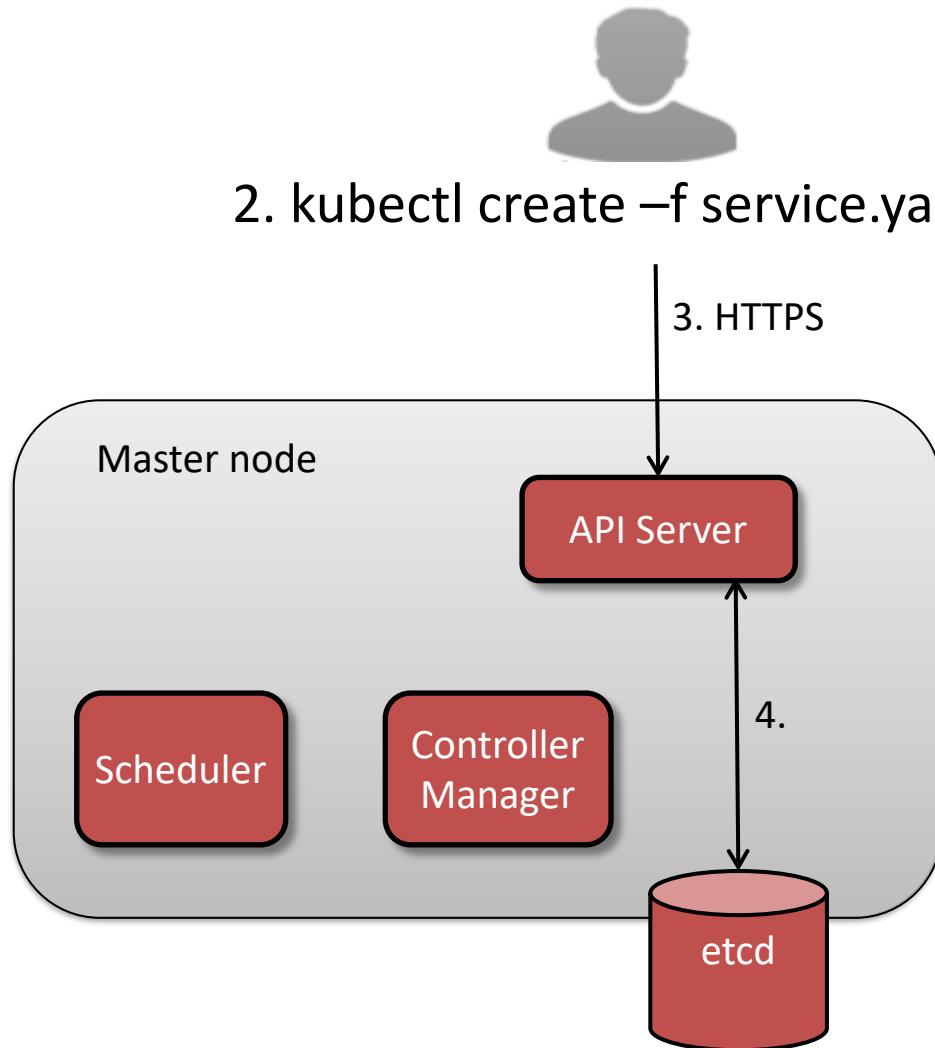

INNOVATION
SOFTWARE
LEARN. EMPOWER. INNOVATE.

Services Management

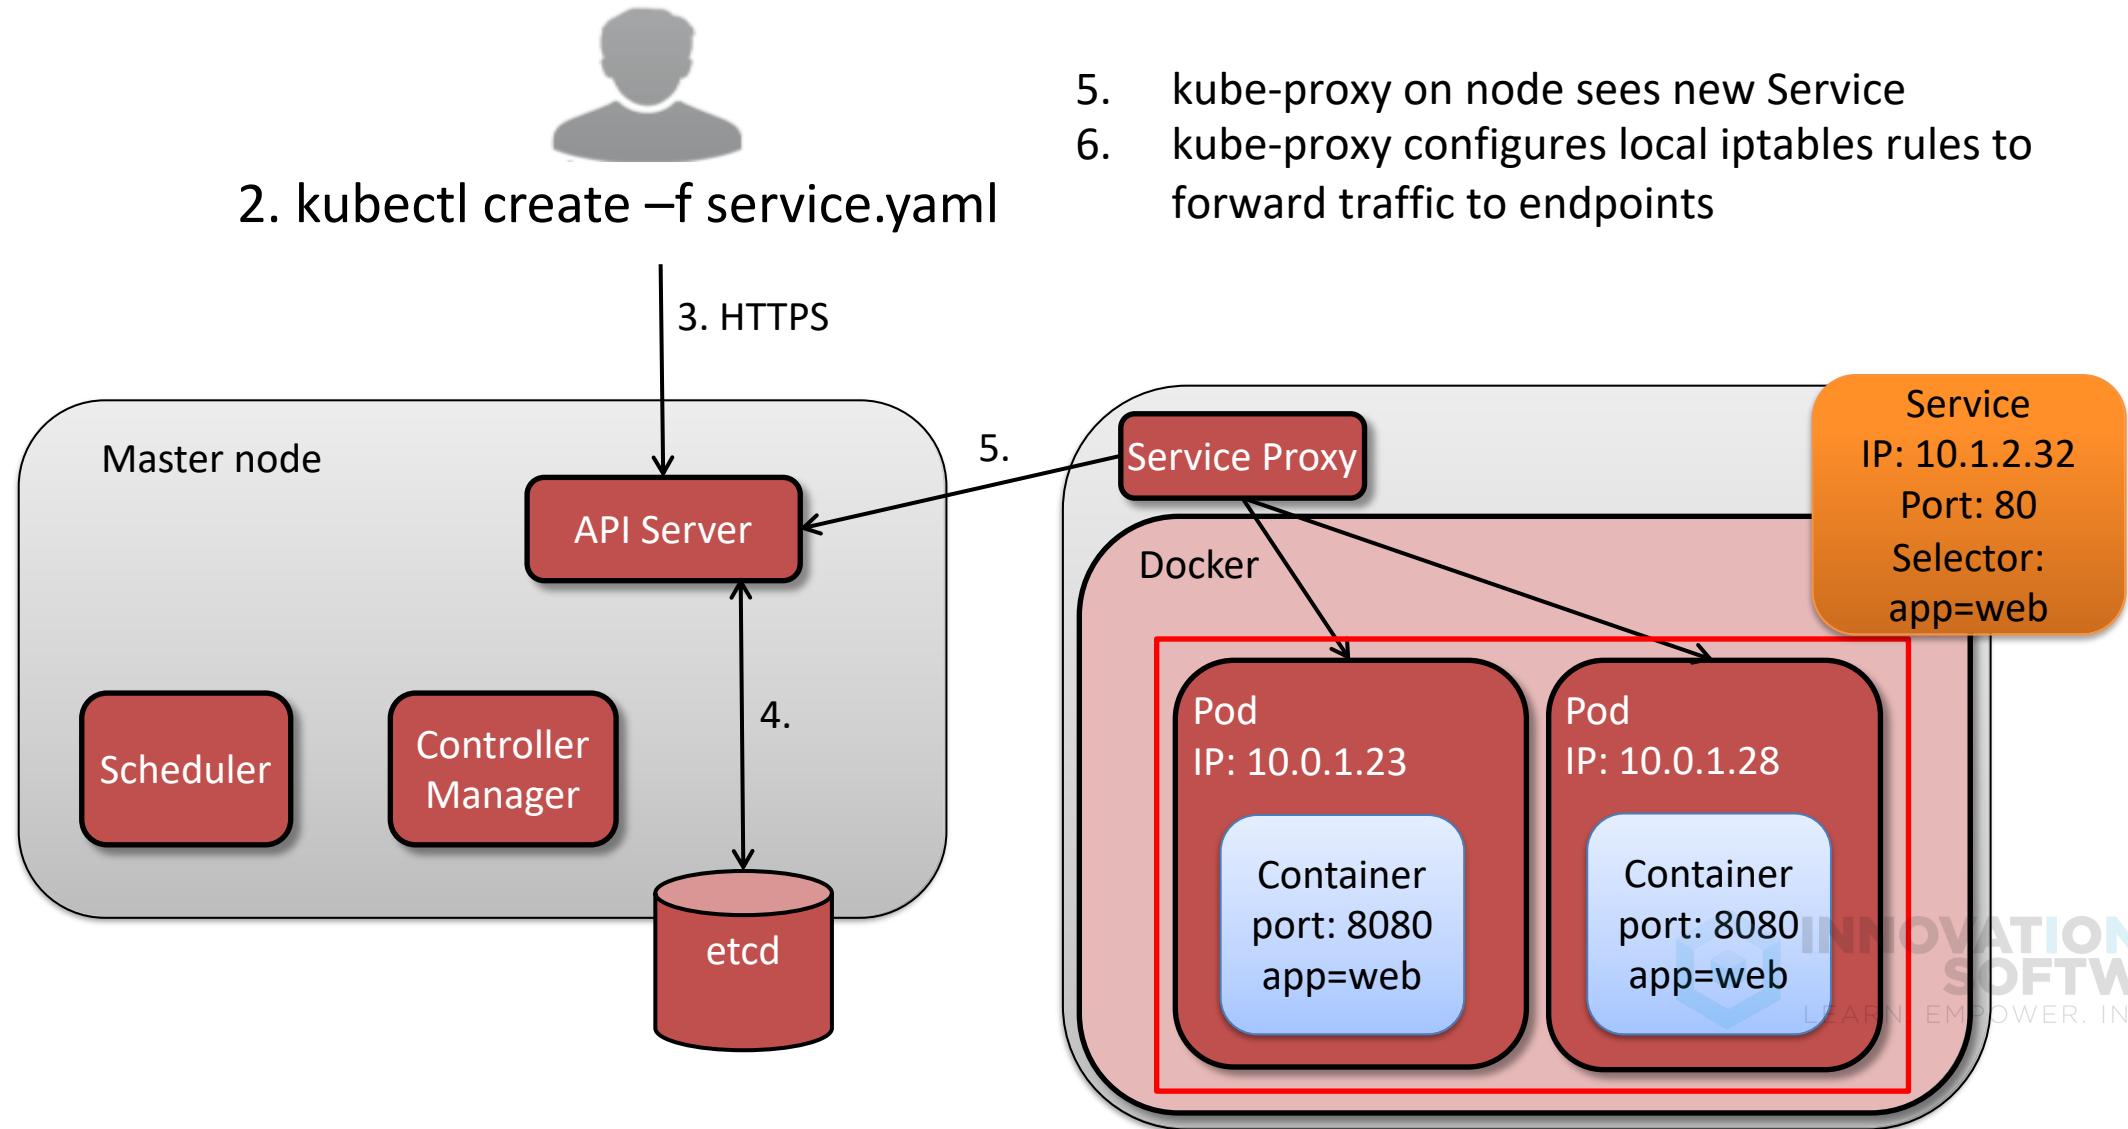

Service Creation Process

1. User writes a Service manifest file
2. User requests creation of Service from manifest via CLI
3. CLI tool marshals parameters into K8s RESTful API request (HTTP POST)
4. kube-apiserver creates new Service object record in etcd

Service Creation Process

Accessing Services Externally

Checking the service external IP

- Configured as type LoadBalancer, a configured cluster will provide an externally accessible IP for your Service

```
$ kubectl get services test-service
NAME      CLUSTER-IP      EXTERNAL-IP      PORT(S)      AGE
test-service  10.3.247.123  104.154.105.198  8080/TCP  4h
```

Deleting Services

Services can be deleted anytime

- Service deletion does not affect pods targeted by the Service's selector
- Can be done referencing the Service name or a manifest for the resource

```
$ kubectl delete -f simpleservice.yaml
```

```
$ kubectl delete service test-service
```

Service Discovery via DNS

Kubernetes advertises services via cluster DNS

- Kubernetes uses a cluster-internal DNS addon to create and manage records for all Services in the cluster
- Pod's DNS search list includes its own namespace and cluster default domain by default

```
$ kubectl get svc
NAME           CLUSTER-IP   EXTERNAL-IP   PORT(S)        AGE
kubernetes     10.0.0.1    <none>        443/TCP       11d
test-service   10.0.0.102   <nodes>       8080:30464/TCP 2d
```

```
kubectl exec -ti busybox1 -- nslookup test-service.default
Server:  10.0.0.10
Address 1: 10.0.0.10 kube-dns.kube-system.svc.cluster.local
```

```
Name:      test-service.default
Address 1: 10.0.0.102 test-service.default.svc.cluster.local
```

Service Discovery via Environment Variables

Kubernetes advertises services via local environment

- When a Pod is started on a node, kubelet will create environment variables for Services in the Pod's namespace and system namespace

```
$ kubectl exec -ti busybox -- printenv | grep SERVICE  
KUBERNETES_SERVICE_HOST=10.0.0.1  
KUBERNETES_SERVICE_PORT=443  
KUBERNETES_SERVICE_PORT_HTTPS=443  
TEST_SERVICE_SERVICE_HOST=10.0.0.102  
TEST_SERVICE_PORT_8080_TCP_PROTO=tcp  
TEST_SERVICE_PORT_8080_TCP_PORT=8080  
TEST_SERVICE_PORT=tcp://10.0.0.102:8080  
TEST_SERVICE_PORT_8080_TCP_ADDR=10.0.0.102  
TEST_SERVICE_SERVICE_PORT=8080  
TEST_SERVICE_PORT_8080_TCP=tcp://10.0.0.102:8080
```

Questions

**INNOVATION
SOFTWARE**
LEARN. EMPOWER. INNOVATE.

Deployments

What is a Deployment?

Kubernetes controller optimal for stateless applications

- Deployments allow you to declaratively manage pods, including replication
- Deployments support
 - Creating, rolling out, and rolling back changes to homogeneous set of pods
 - Scaling set of pods out and back declaratively
- Deployments include
 - Implicit Replica Set controller to handle pod replicas
 - Template spec of pods to be created and managed – no need to separately create pods
- Deployments used for web applications, mobile back-ends, API's

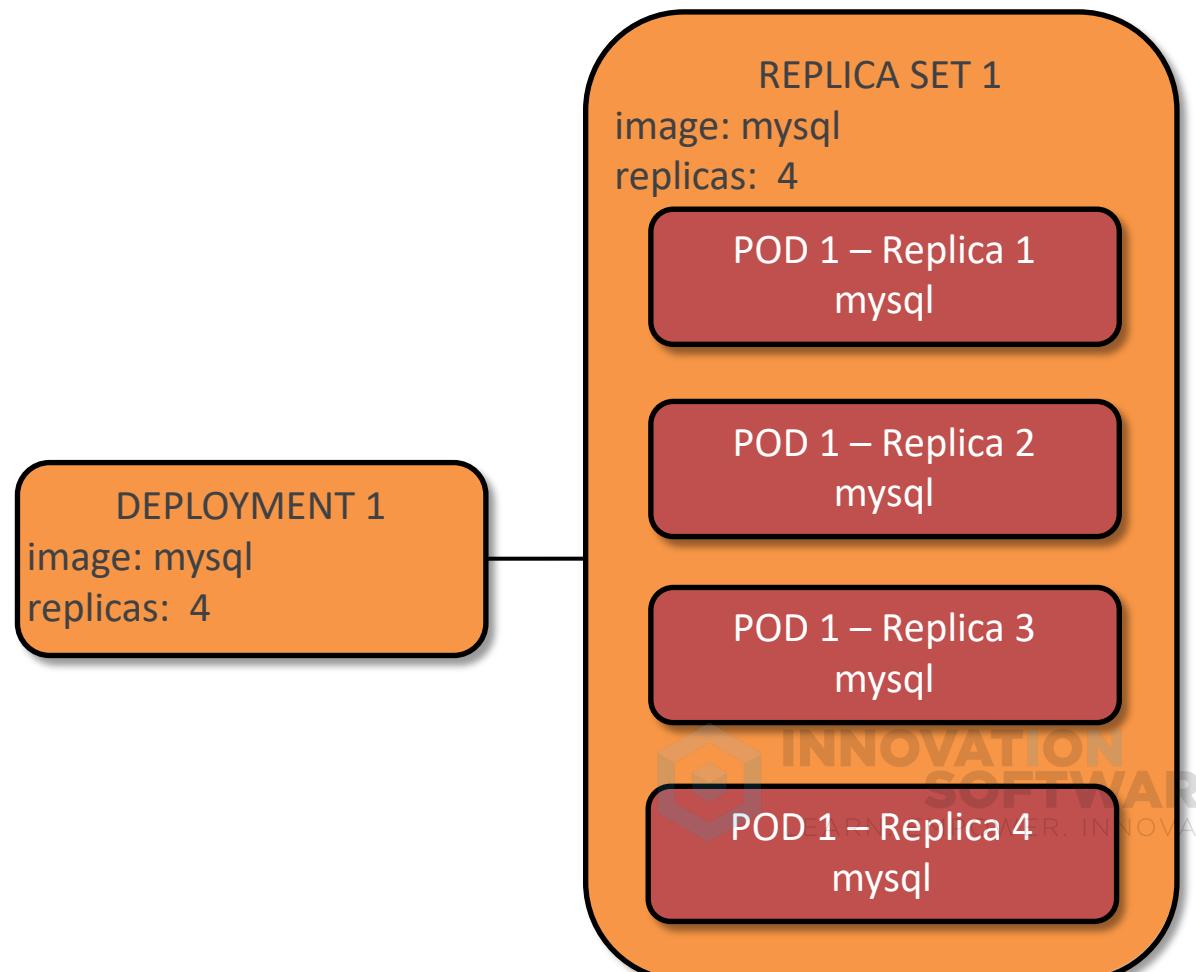

What if my Application isn't Stateless?

- Kubernetes provides other controller objects for applications that need different deployment schemes
- **StatefulSets** (previously PetSets) control deployment of pods for applications that need more stable deployment contexts
 - Pods in StatefulSets have unique ordinal, stable network identity and stable storage using persistent volumes
 - When pods are deployed, they are created in sequence of ordinals 1..N
 - Pod N must be running and ready before Pod N+1 is deployed
 - When pods are destroyed, they are terminated in reverse sequence N..1
- **DaemonSets** ensure that a replica of a specified pod is running on every node (or every selected node) in the cluster
- **Jobs** manage sets of pods where N must run to successful completion

Deployments Control ReplicaSet Controllers

Definition of how many replicated Pods should exist

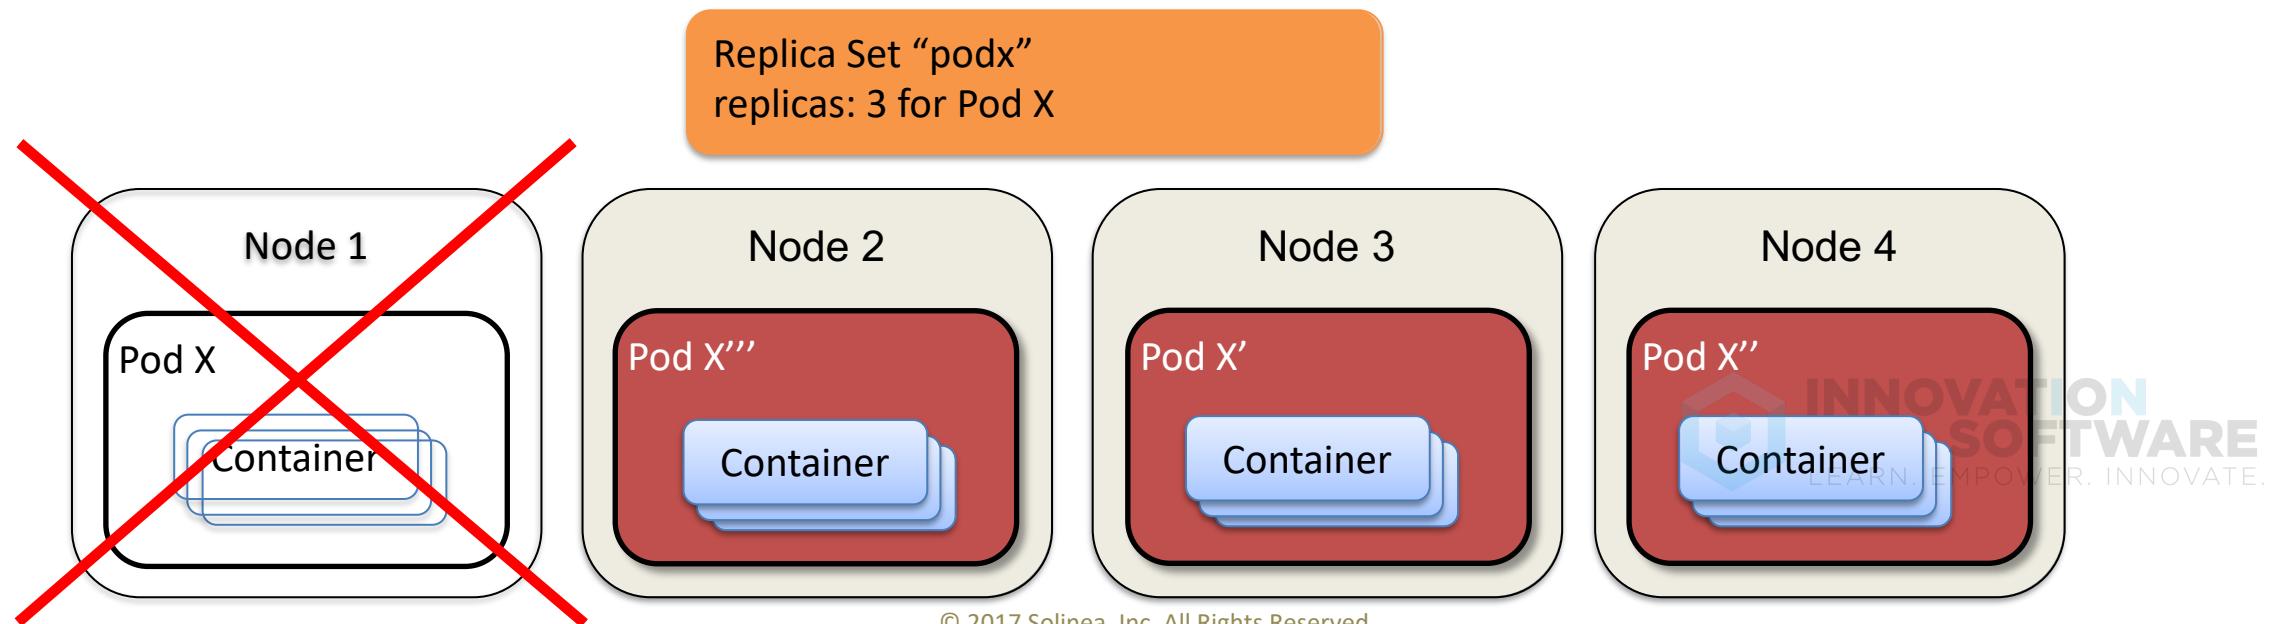

- Deployment creates and manages a Replica Set that manages a set of pods
- Replica count can be adjusted as needed to scale the Replica Set out and back
- Replica Set successor to the ReplicationController object

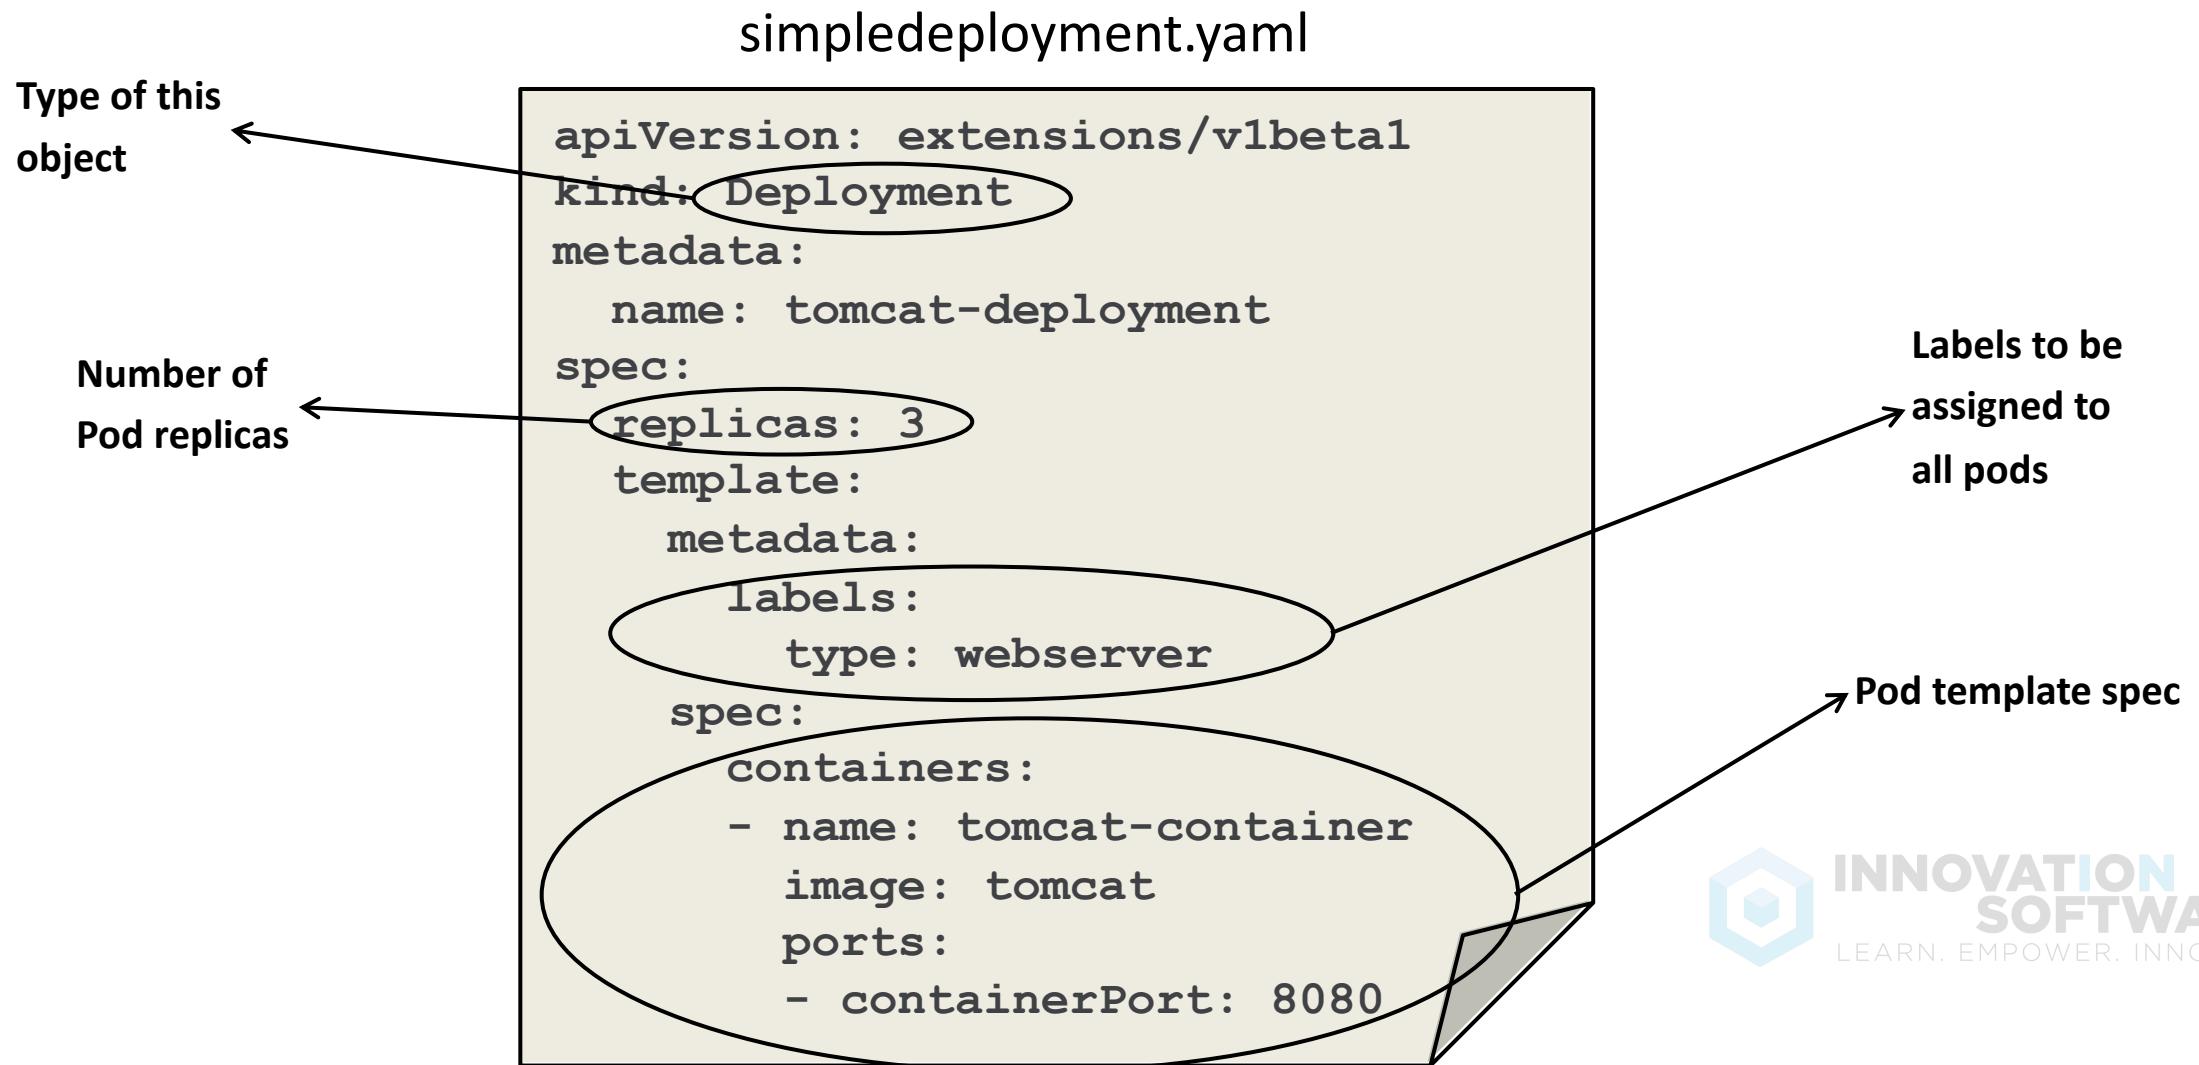

What is a Replica Set?

Provides scaling and high availability

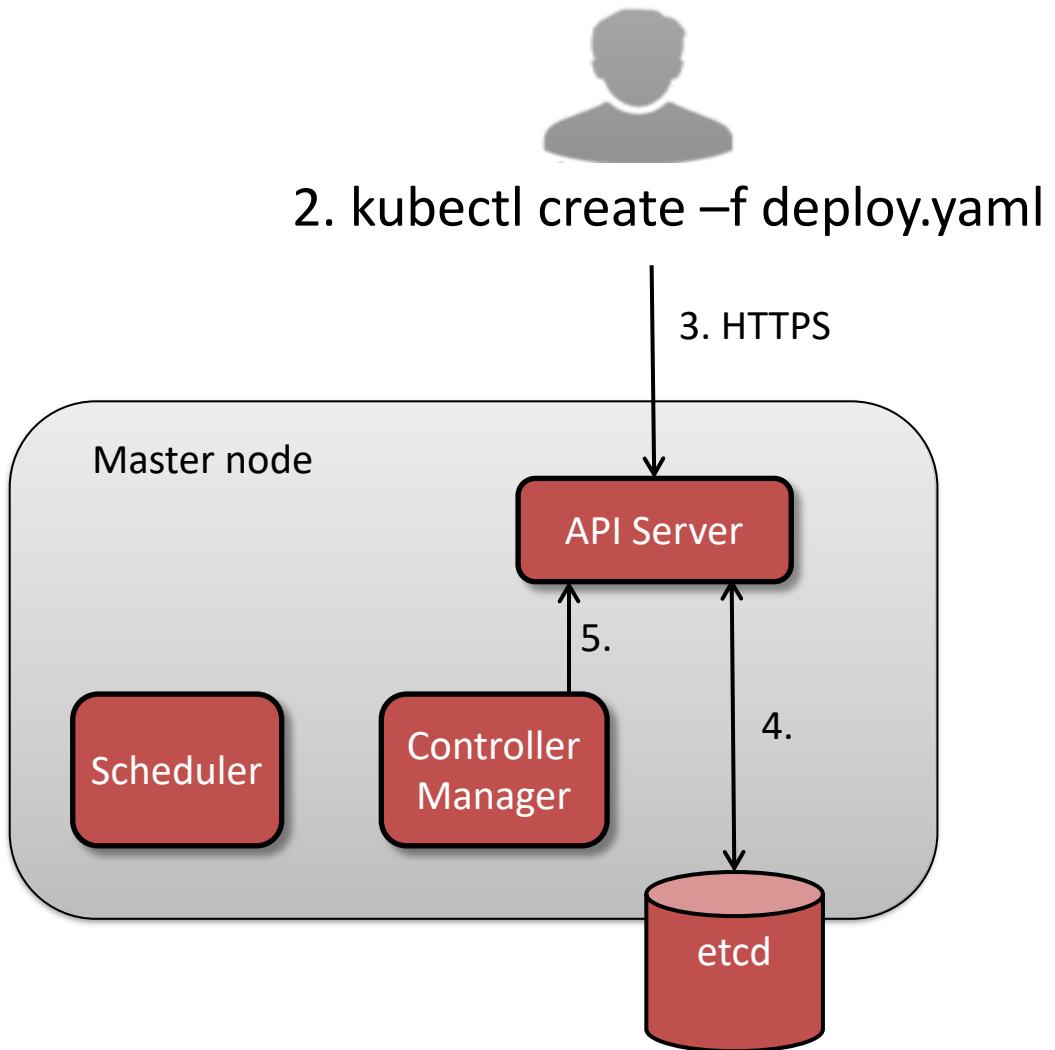

- Replica count can be changed to provide scaling on demand as needed
- If the node hosting a pod fails, the Kubernetes cluster will recreate the pod elsewhere to achieve the target number of replicas

Examining a Deployment Manifest File

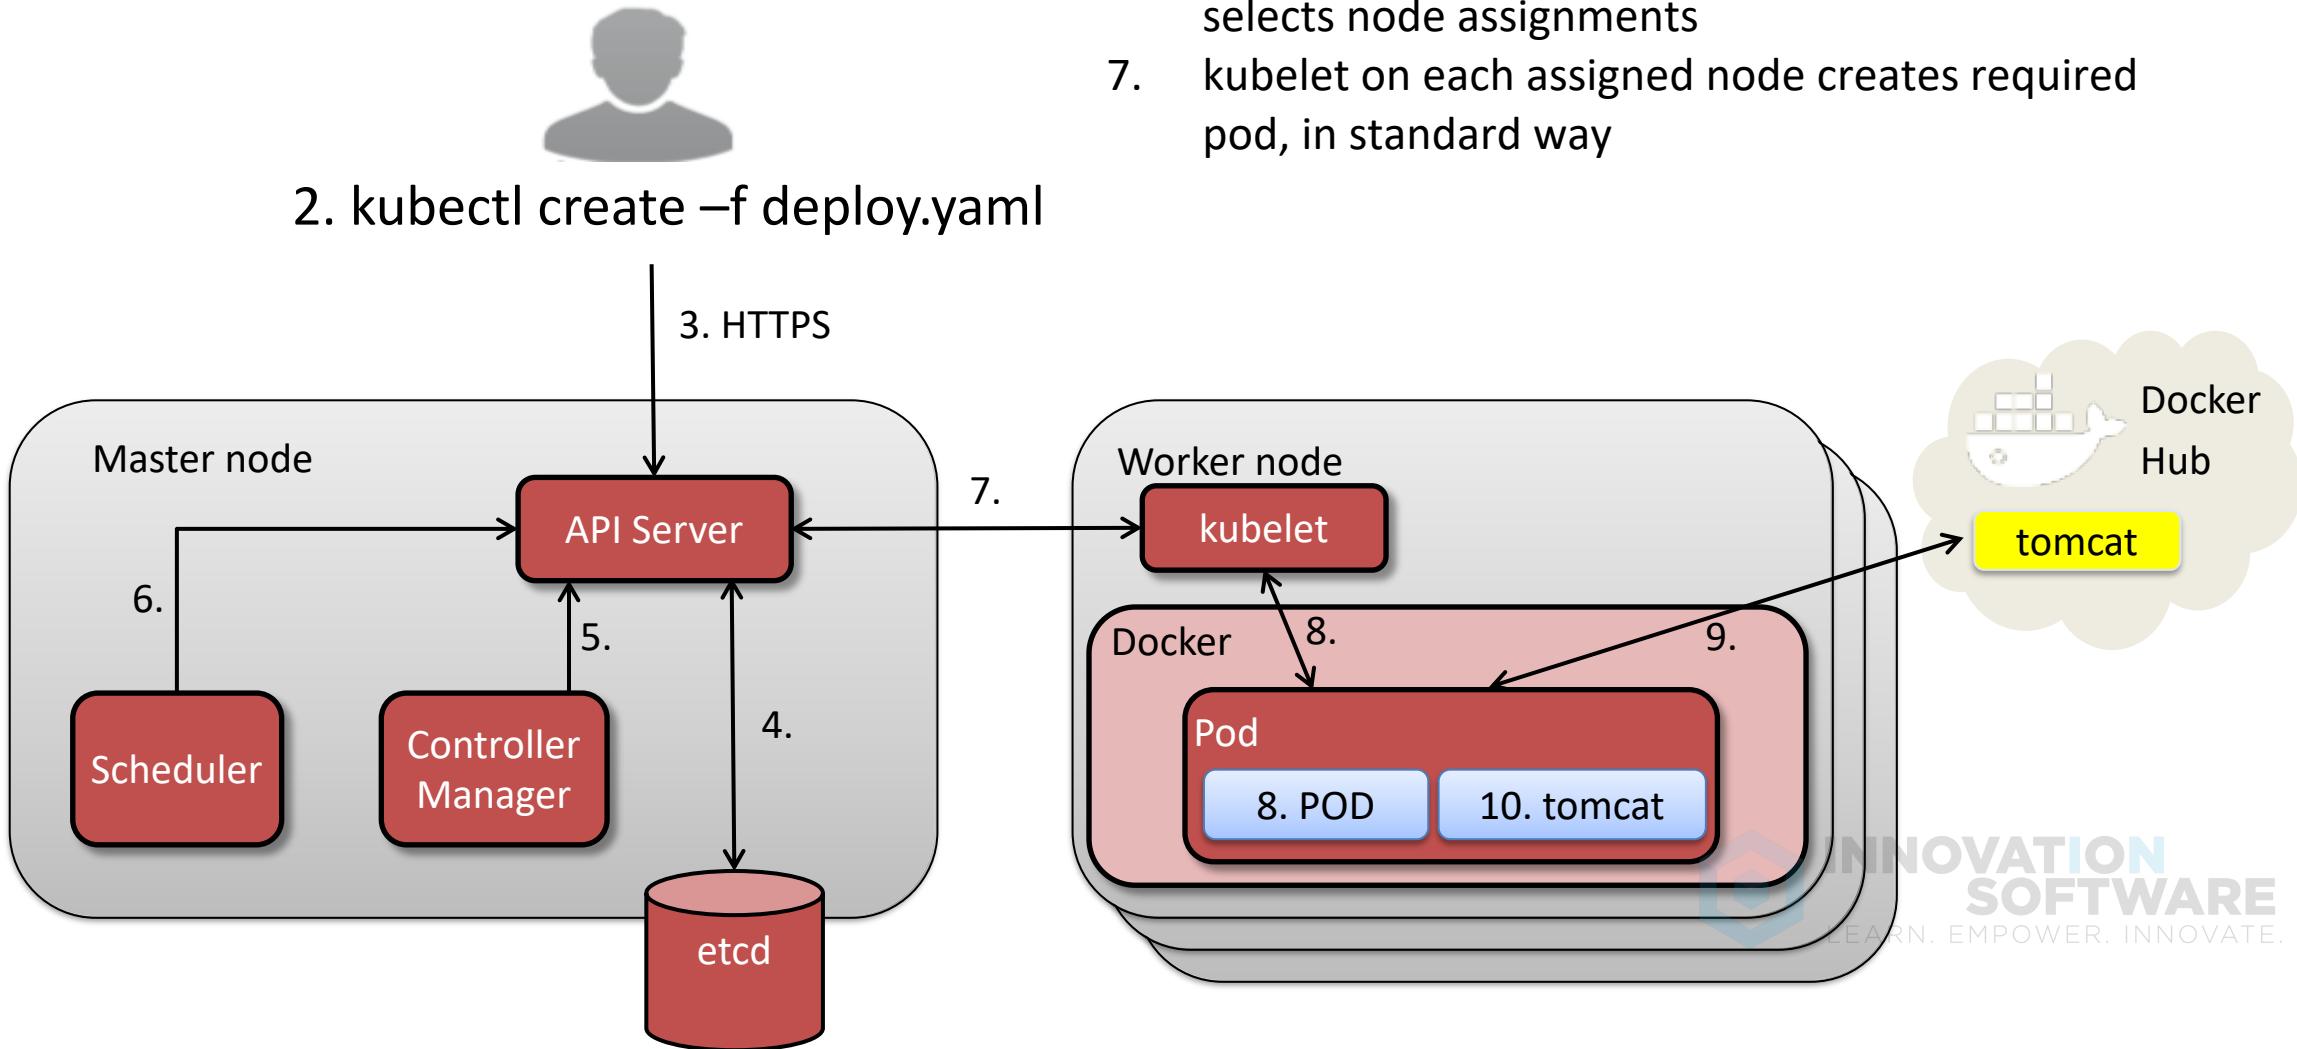

Deployment Creation Process

1. User writes a deployment manifest file
2. User requests creation of deployment from manifest via CLI
3. CLI tool marshals parameters into K8s RESTful API request (HTTP POST)
4. kube-apiserver creates new deployment object record in etcd, and new Replica Set object
5. kube-controller-manager sees new Replica Set and
 - Evaluates state of existing vs. required replicas
 - Submits pod creation requests to API to create required number of replicas

Deployment Creation Process

Deployments Management

Deployments Control ReplicaSets

The deployment creates a ReplicaSet that controls pod creation

Deployment name defined in the yaml	Number of replicas defined in the spec	Number of existing pods	Number of Pods that match the Deployment config	Actual number of Pods running
\$ kubectl get deployments NAME tomcat-deployment	DESIRED 3	CURRENT 3	UP-TO-DATE 3	AVAILABLE 3

\$ kubectl get rs	NAME	DESIRED	CURRENT	UP-TO-DATE	AVAILABLE	AGE
	tomcat-deployment-1699985759	3	3	3	3	2m

Replica Set Details

Replica Set name is <Deployment name>-<pod template hash value>

```
$ kubectl describe replicaset tomcat-deployment-1699985759
```

Name: tomcat-deployment-1699985759

Namespace: default

Image(s): tomcat

Selector: pod-template-hash=1699985759,type=webserver

Selector uses labels
from pod template
and template hash

Labels: pod-template hash-1699985759

type=webserver

Replicas: 3 current / 3 desired

Pods Status: 3 Running / 0 Waiting / 0 Succeeded / 0 Failed

...

Pod Naming

Pod name is <Replica Set name>-<pod unique random string>

```
$ kubectl get pods
NAME                               READY   STATUS
tomcat-deployment-1699985759-h11sz 0/1     ContainerCreating
tomcat-deployment-1699985759-ka13j 0/1     ContainerCreating
tomcat-deployment-1699985759-u03b5 1/1     Running
```

```
$ kubectl get pods
NAME                               READY   STATUS
tomcat-deployment-1699985759-h11sz 1/1     Running
tomcat-deployment-1699985759-ka13j 1/1     Running
tomcat-deployment-1699985759-u03b5 1/1     Running
```

Pod name based on
Replica Set name

Random string to
differentiate Pods

Modifying a Deployment to Trigger a Rollout

Multiple ways to change a Deployment configuration

- Change the manifest file and apply it via *kubectl apply*
- Change specific Deployment attribute via *kubectl set*
- Edit the Deployment config in the cluster via *kubectl edit*
- **Any changes to the Pod template will trigger a rollout of the Deployment to create and replicate new Pods with the new template**
 - This means any changes – even things like pod labels!

Pausing a Deployment

Pause a Deployment to temporarily halt rollout of updated pods

```
$ kubectl set image deployment/tomcat-deployment tomcat-container=tomcat:8.5.5;  
kubectl rollout pause deployment/tomcat-deployment  
deployment "tomcat-deployment" image updated  
deployment "nginx-deployment" paused
```

```
$ kubectl rollout resume deployment/tomcat  
deployment "tomcat-deployment" resumed
```

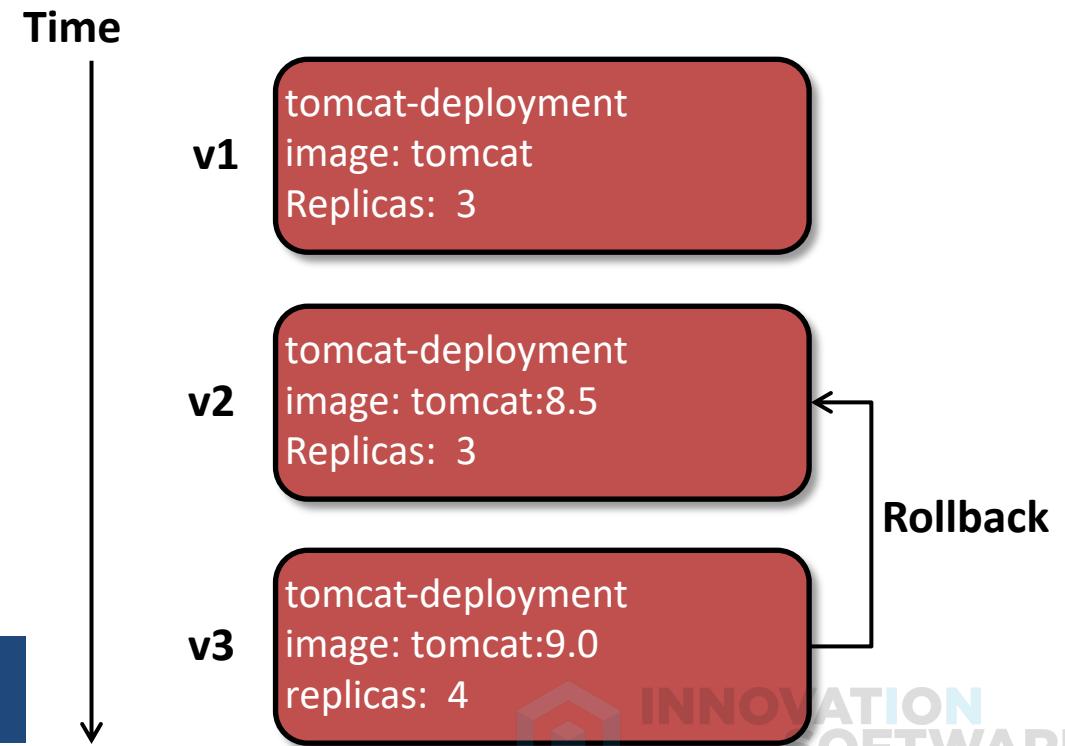

```
kubectl rollout status deployment/tomcat-deployment  
deployment "tomcat-deployment" successfully rolled out
```

Checking Deployment Rollout History

Kubernetes tracks revisions made to a Deployment

- Users can query history of a deployment and see how many versions existed, and what change was made
 - Need to use *-record* flag on kubectl to record details of change commands
- History allows you to roll back state of a Deployment to a previous version

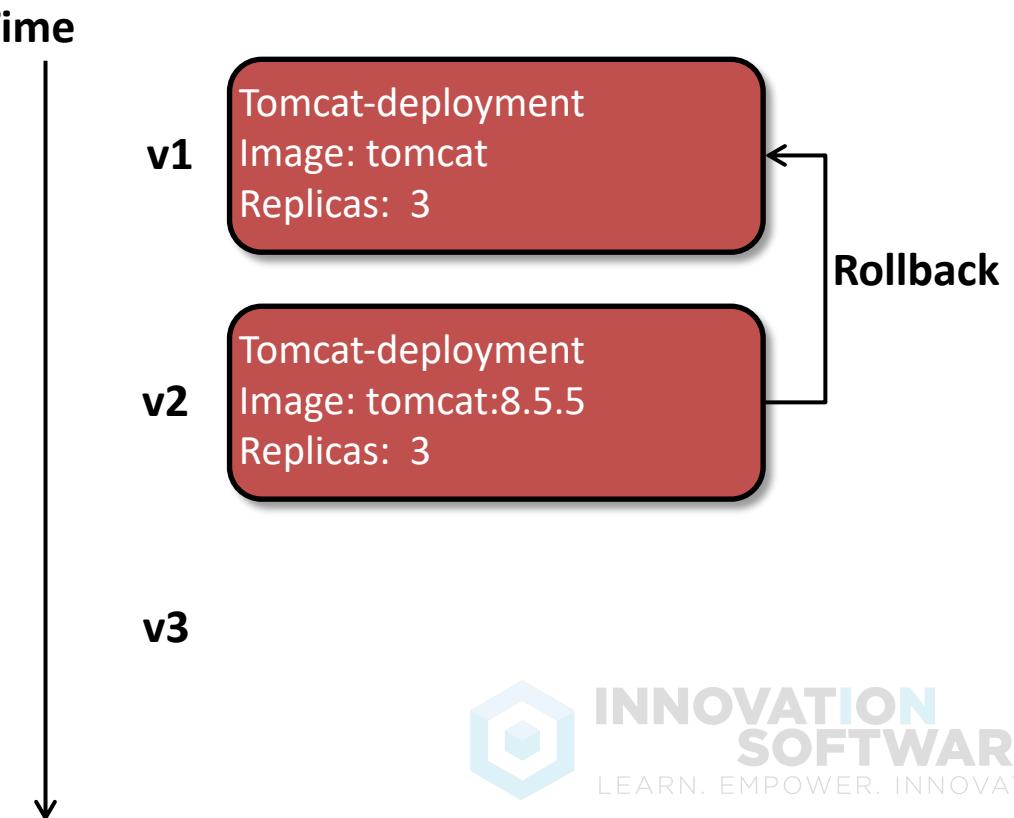

```
$ kubectl rollout history deploy/<deployment>
```

Rolling back a Deployment

Undoing Deployment changes via rollback operation

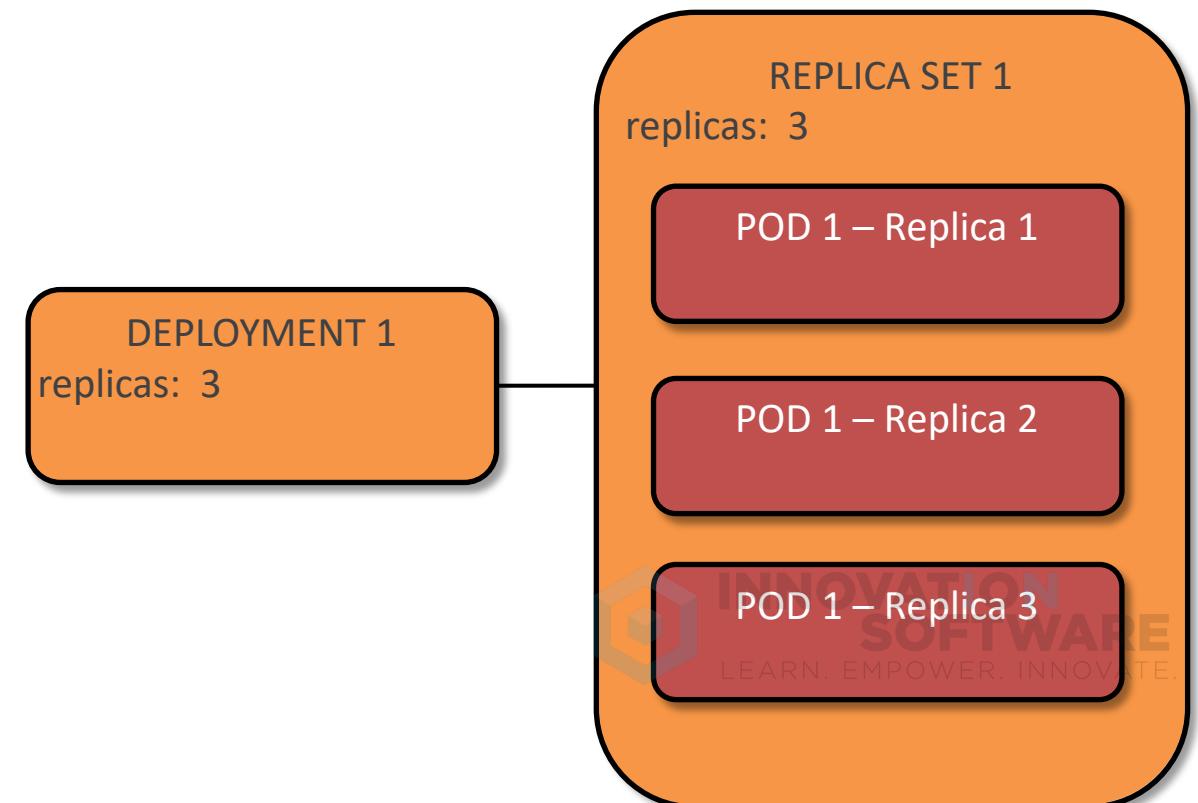

- You can undo the last change or roll back to a specific version
- The revision order will be changed to reflect the change
 - In this example, revision v1 will become the new revision v3
 - Version numbers increase monotonically
- Revision state stored in the corresponding Replica Sets

Deleting a Deployment

Deleting a Deployment will delete its Replica Set and all its Pods

- By default, when Deployment is deleted, its Replica Sets are deleted
- Deletion of Replica Set cascades to deletion of pods managed by the rs
- Any Replica Sets reflecting previous versions of the Deployment will also be deleted

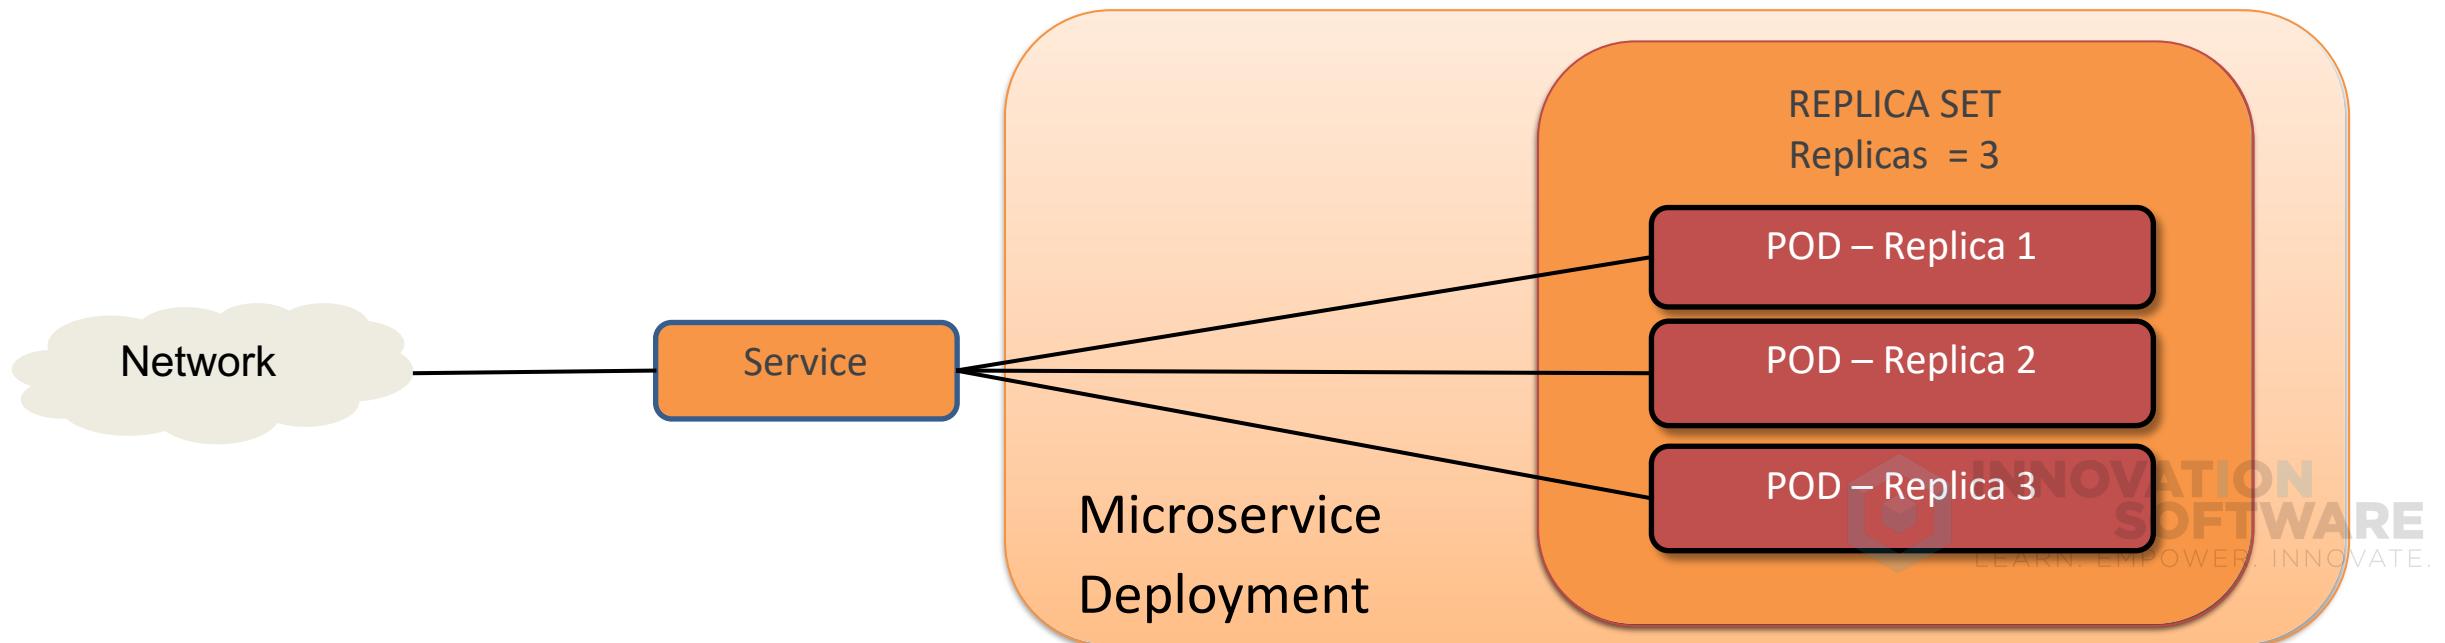

Scaling Deployments

Kubernetes Deployments for Microservices

Kubernetes is perfect for Microservices management

- Applications built as services or collections of microservices easily modeled using Kubernetes Deployment and Service resources
- Key property is that application or component can be scaled horizontally

Basic Microservices Principles

- Application is composed of in(ter)dependent, independently deployable components
 - E.g. containerized components packaged as Docker images
- Design of application is service-oriented, with information exchange between components via standard interfaces, e.g.
 - RESTful APIs
 - AMQP messaging
- Maximize use of stateless components that can be scaled horizontally via replication
 - Horizontal scaling provides elastic capacity for handing demand

Application Scaling Strategies

Several ways to achieve scalability

- **Pre-defined application scale:** application deployed with a predefined, static number of resources => not the Kubernetes way
- **Manual scaling:** deployment scale reconfiguration driven by operator
- **Auto-scaling:** automatic scaling of resources based on a defined trigger (number of hits, CPU usage, etc)

Application Scaling Strategies

Manual scaling

- K8s supports manual scaling of Deployment to adjust replica count
- Operator just needs to adjust declaration of how many replicas are desired, and K8s system will manage to that number
 - Pod creation and placement completely automatic
 - Pods automatically re-created if nodes fail

```
$ kubectl scale --replicas=2 deployment/tomcat
```

```
$ kubectl scale --replicas=8 deployment/tomcat
```

```
$ kubectl scale --replicas=4 deployment/tomcat
```

```
$ kubectl edit deployment/tomcat
```

```
$ kubectl apply -f simpledeployment.yaml
```

Application Scaling Strategies

Auto-scaling in Kubernetes

- Kubernetes has a controller object for automatic scaling of Deployments (or Replica Sets or ReplicationControllers)
- HorizontalPodAutoscaler is control loop to adjust scale of pod set depending on one or more metrics, evaluated at configurable interval (default 30s)
 - Requires Heapster to be deployed on the cluster to provide metric data
 - Metrics include CPU and RAM utilization for pods
- Typical scenario: increase Deployment replica count when average Pod CPU utilization is above threshold value for specified period of time
- Note: application must support horizontal scaling!

Automatic Scaling of a Deployment

Creating a HorizontalPodAutoscaler resource

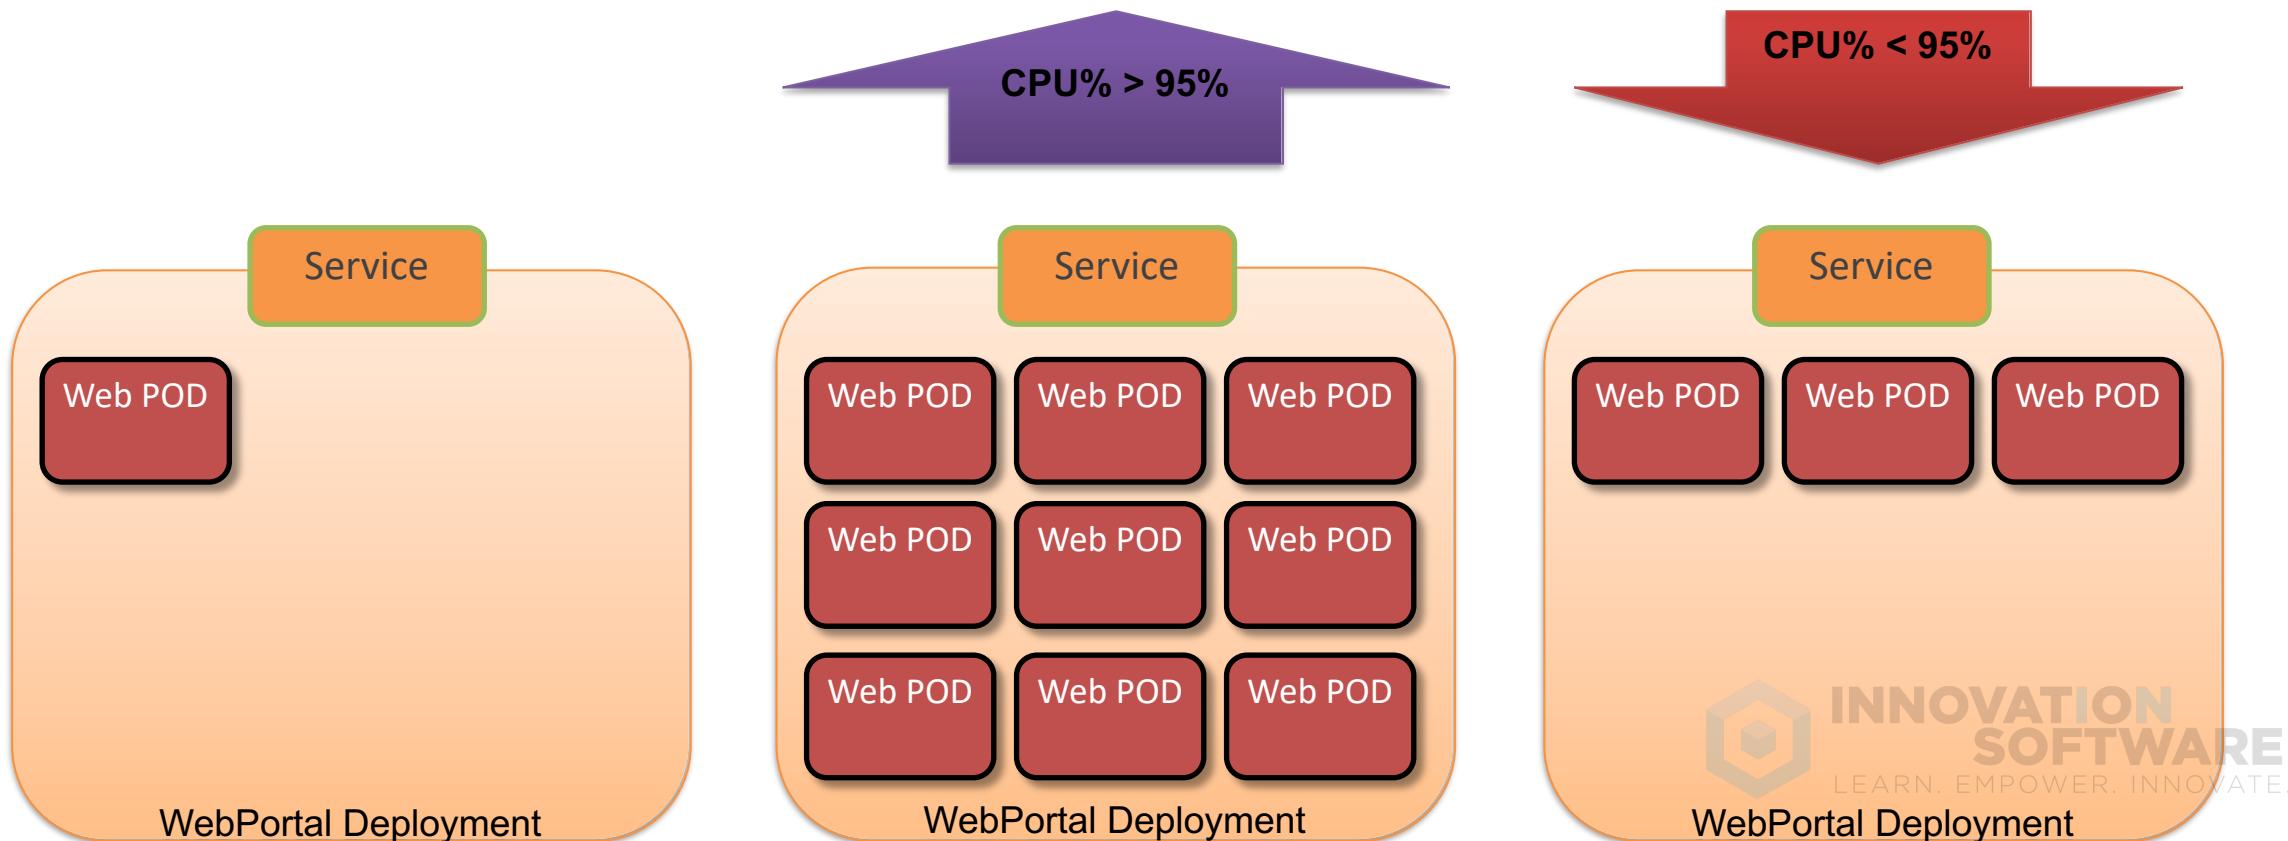

- The hpa is created similarly to any other Kubernetes resource
 - Use a manifest file for source tracking
 - Can create directly with *kubectl*
- 30 seconds is the default for considering the threshold
- Scaling is metrics-driven, either resource metrics from Heapster or custom metrics API

```
apiVersion: autoscaling/v1
kind: HorizontalPodAutoscaler
metadata:
  name: tomcat-autoscaler
spec:
  maxReplicas: 10
  minReplicas: 2
  scaleTargetRef:
    kind: Deployment
    name: tomcat-deployment
  targetCPUUtilizationPercentage: 75
```

simplescaler.yaml

Auto-Scaling of a Deployment

HorizontalPodAutoscaler with a 95% CPU usage threshold

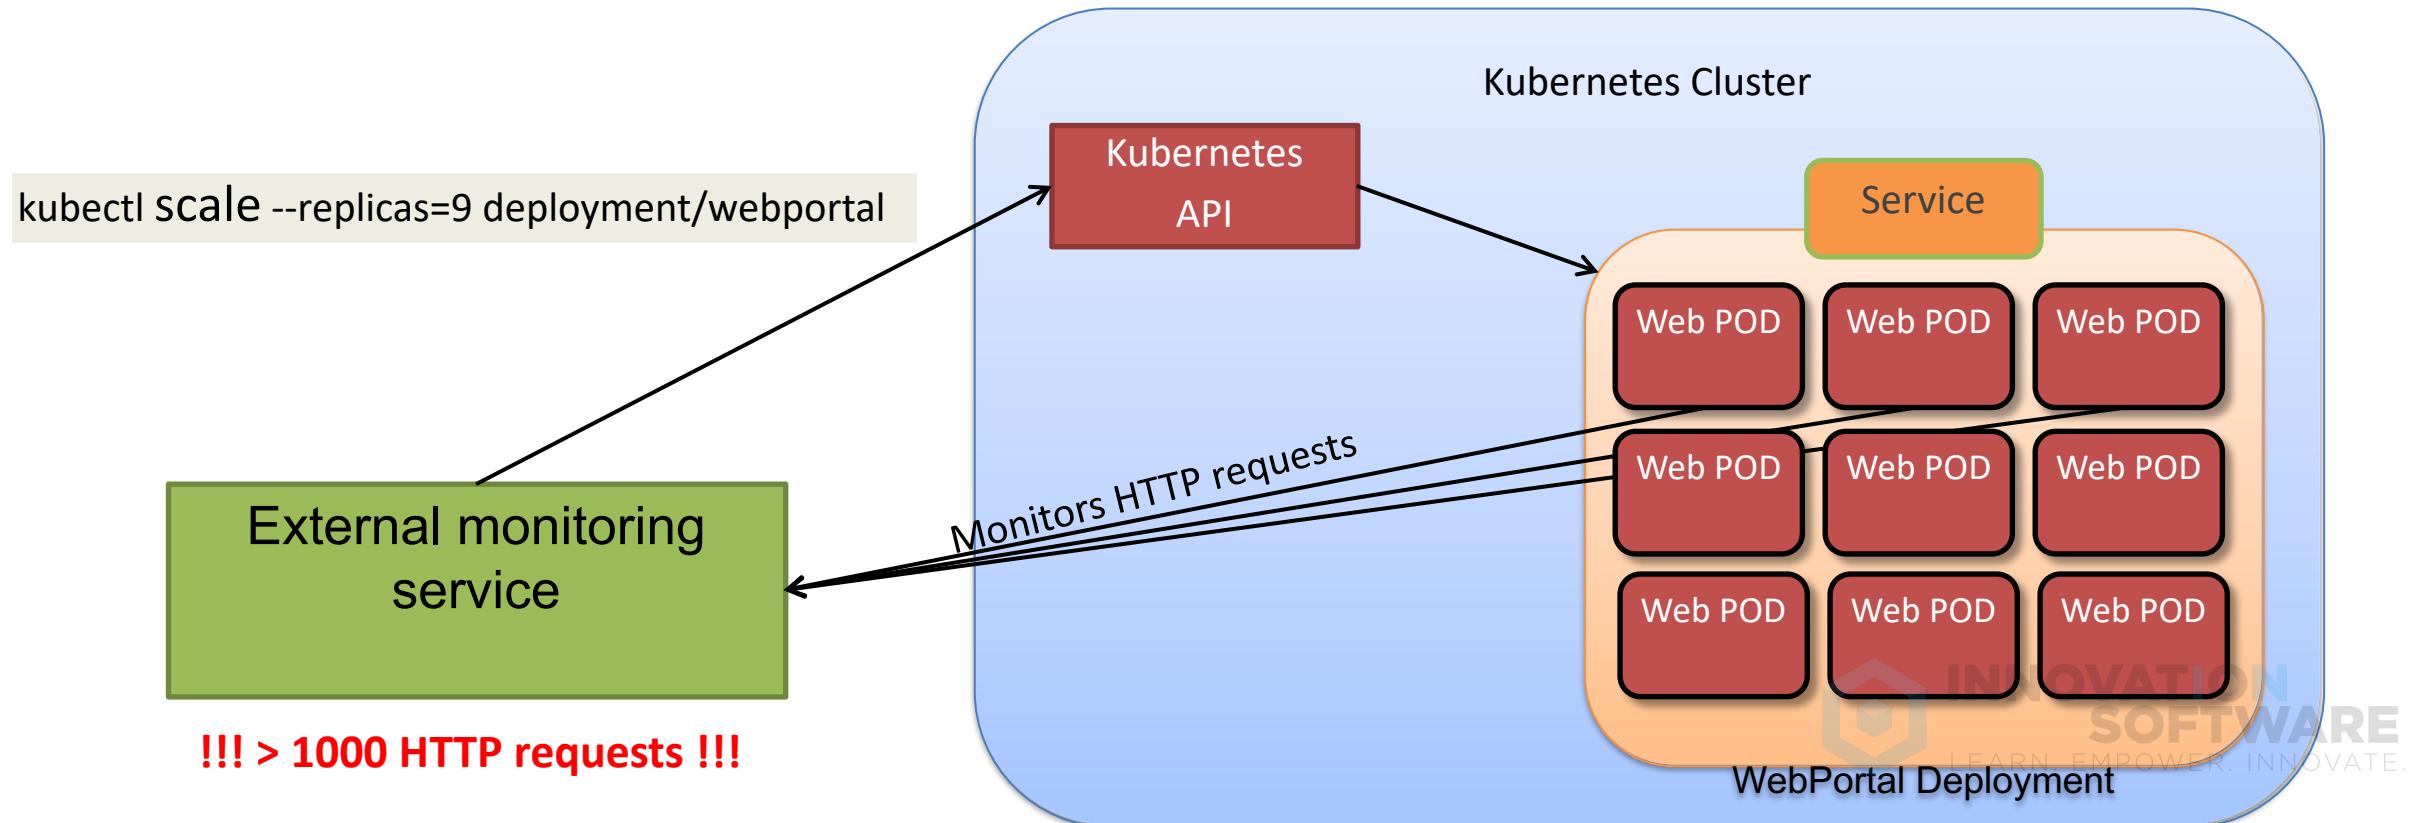

Application Scaling Strategies

Externally-driven auto-scaling

- Kubernetes API can be used to change Deployment replica counts remotely
- Any monitoring application that can send REST calls (e.g. Nagios) could be used to drive automatic scaling externally
- Very flexible approach, but more complex to implement
- **Needs robust testing before going into production**

Application Scaling Strategies

Auto-scaling driven by external system

Deployment Strategies Overview

What is a Deployment Strategy?

Approaches to manage risks on updating Deployments

- On each Deployment update/change, all pods in the deployment will be deleted and recreated
- Recreation process can have service impacts, especially for large Deployments
- A Deployment strategy defines how this rebuild process is done, to minimize downtime due to application failures or malfunctions

Types of Deployment Strategies

Kubernetes supports two basic strategies, but users can also leverage multiple Deployments when applying changes

- Strategies for single Deployments
 - Recreate
 - RollingUpdate
- Strategic approaches using two Deployments with a Service
 - Canary deployments
 - Blue/Green deployments

Each approach has a specific behavior and advantages/disadvantages.

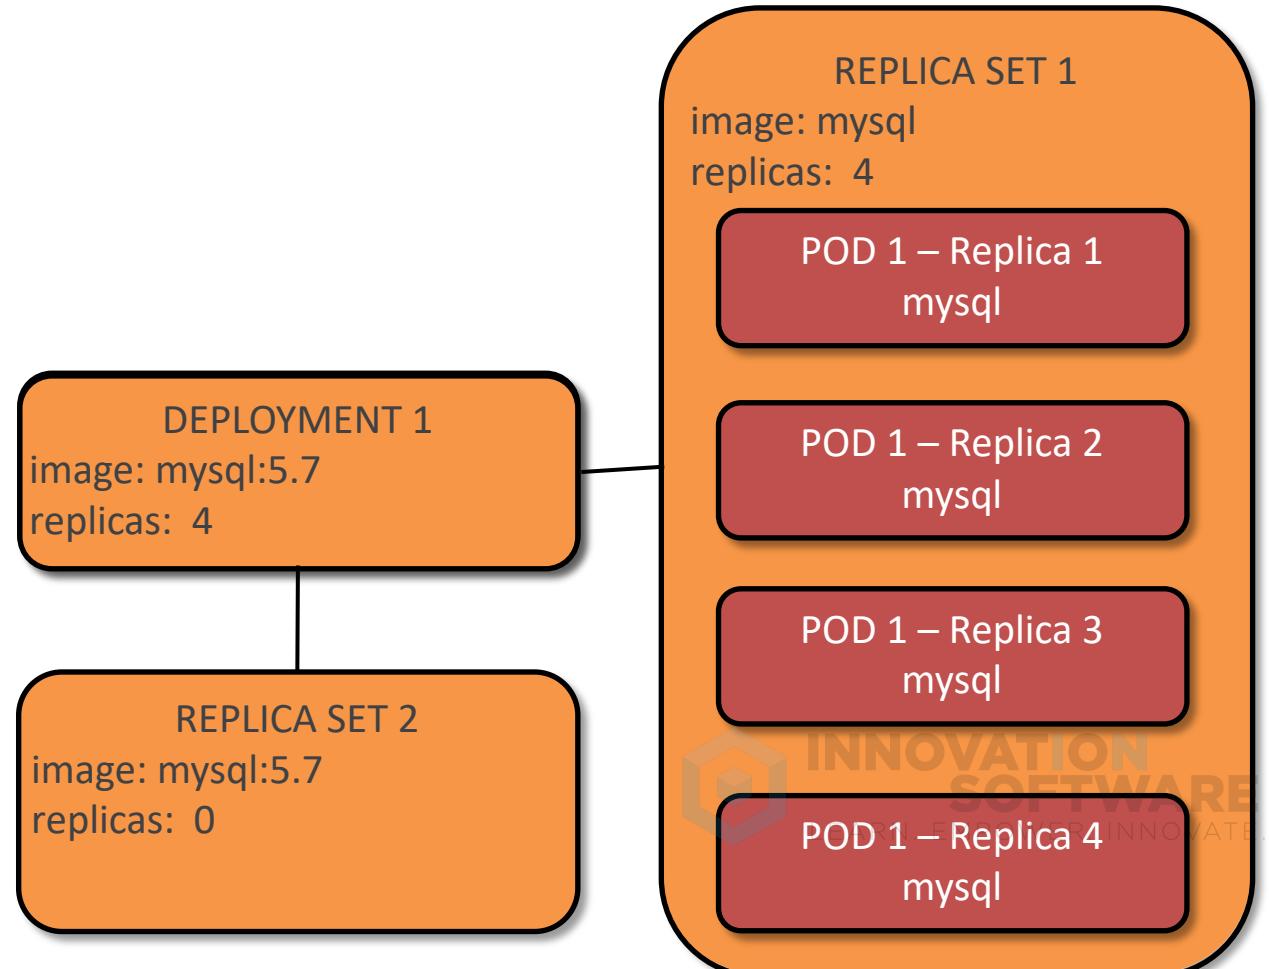

Deployment Strategy: Recreate

Deployment Strategy: Recreate

Simplest strategy for deployments

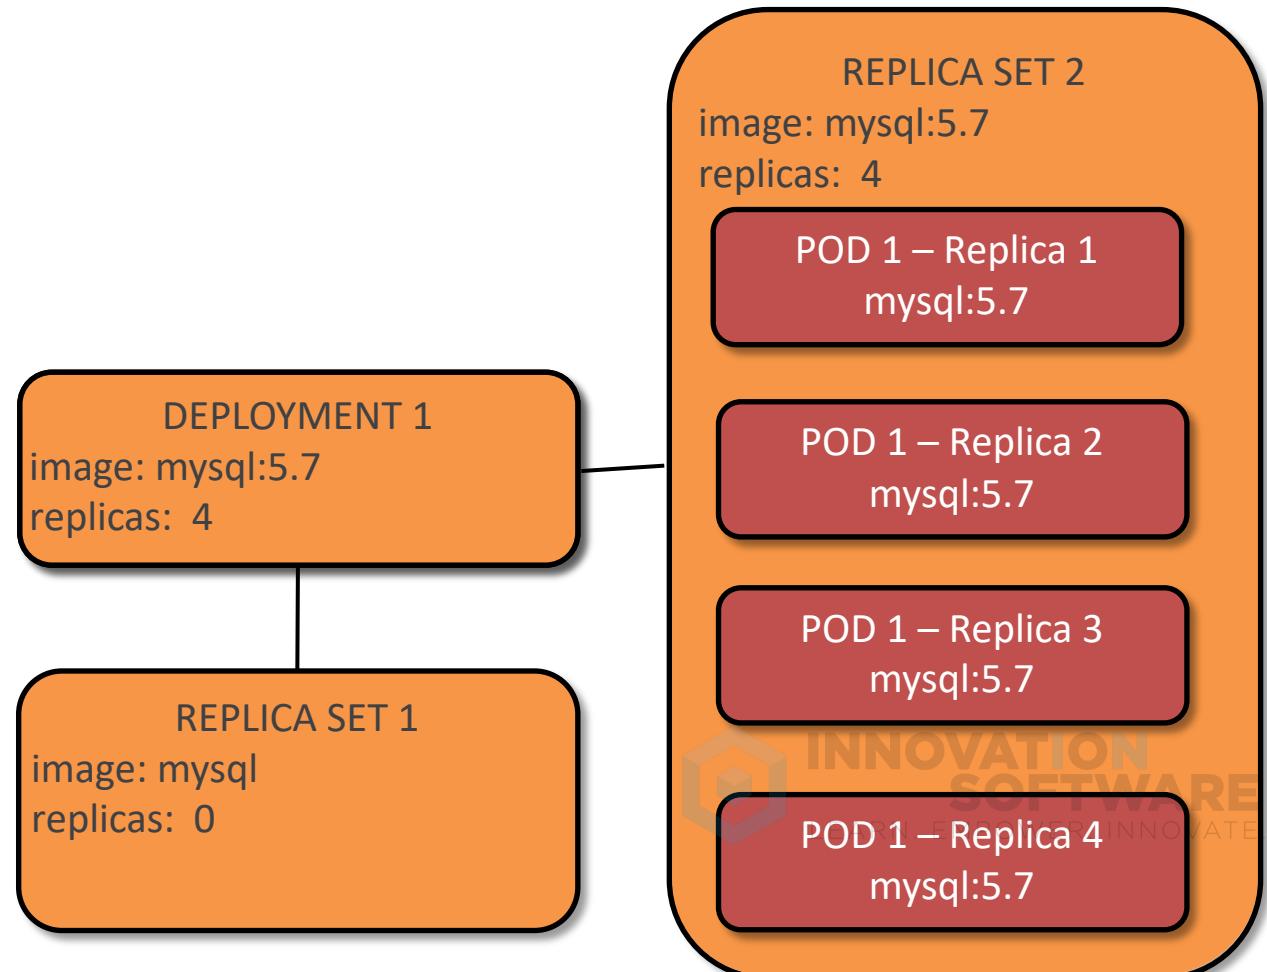

- When a change is made to a Deployment's spec, all Pods are removed and then recreated
 - Old Replica Set pods are killed
 - Then, new Replica Set starts pods
- May lead to downtime during the process while new pods are started

Deployment Strategy: Recreate

Simplest strategy for deployment updates

- When a change is made to a Deployment's template, all Pods are removed and then recreated
 - Old Replica Set pods are killed
 - New Replica Set starts pods
- May cause downtime due to delay between old pods terminating and new pods becoming available

Deployment Strategy: Recreate

Strategies are defined in the spec of a Deployment

- **strategy** parameter in Deployment spec sets the strategy to be used for updates
- If no parameter value is set, the default is **RollingUpdate**

```
apiVersion: extensions/v1beta1
kind: Deployment
metadata:
  name: tomcat-deployment
spec:
  replicas: 3
  strategy:
    type: Recreate
  template:
    metadata:
      labels:
        type: webserver
    spec:
      containers:
        - name: tomcat-container
          image: tomcat
          ports:
            - containerPort: 8080
```

Deployment Strategy: RollingUpdate

Deployment Strategy: RollingUpdate

RollingUpdate is DEFAULT strategy for Deployments

- When a change is made to the Deployment, the old Replica Set pods are scaled down as new pods are created by the new Replica Set
- A minimum number of running Pods is specified, so the Deployment will never be totally out of Pods to respond to service requests
- During the update process, the requested replica count may be temporarily exceeded

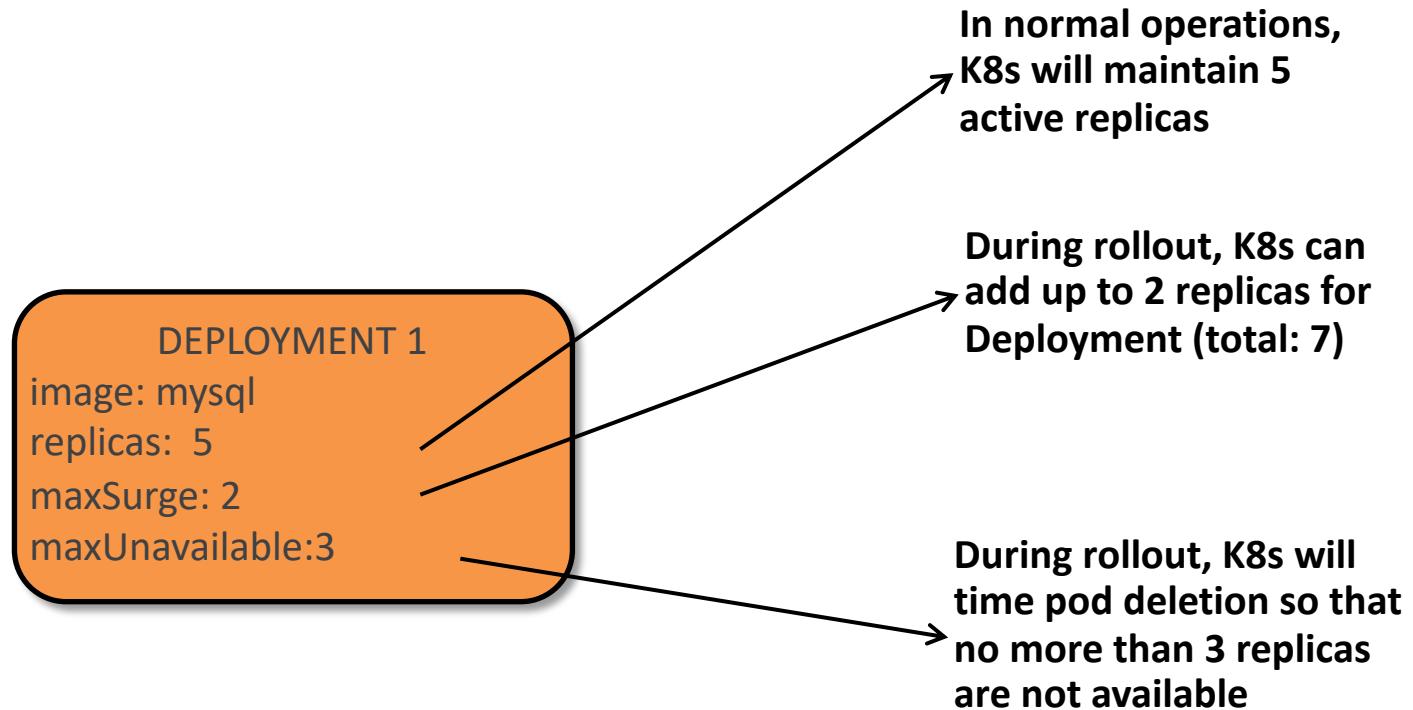

Deployment Strategy: RollingUpdate

Configure parameters to control the update process

```
...  
  metadata:  
    name: tomcat-deployment  
  spec:  
    replicas: 3  
    strategy:  
      type: RollingUpdate  
      rollingUpdate:  
        maxSurge: 25%  
        maxUnavailable:10%  
    template:  
      metadata:  
        labels:  
          type: webserver  
...  
...
```

- **maxSurge**: number or percentage of additional Pods that can be created exceeding the replica count during update
 - Default value of 25%
- **maxUnavailable**: number of Pods that can be unavailable during the update
 - Default value of 25%

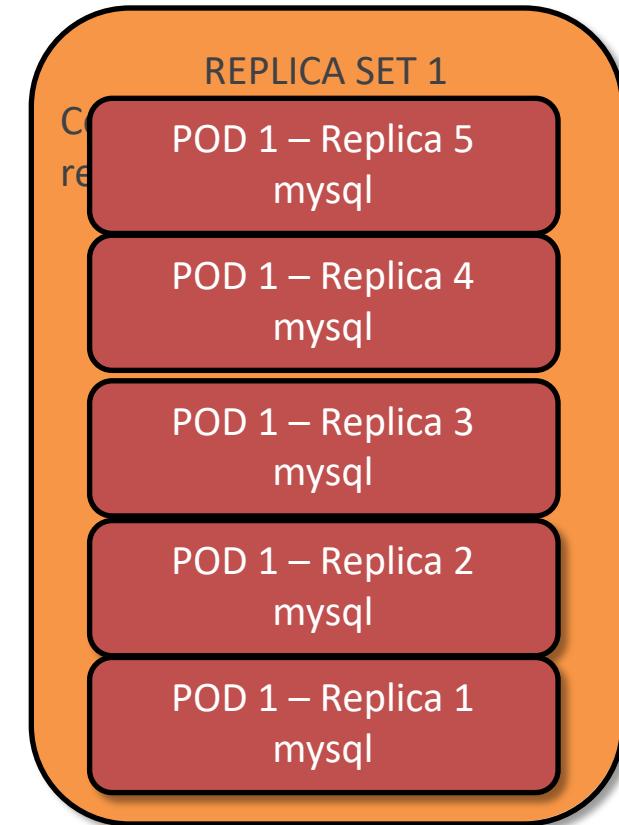

Deployment Strategy: RollingUpdate

Deployment Strategy: RollingUpdate

Initial State

DEPLOYMENT 1

replicas: 0

Updating Using Multiple Deployments

RollingUpdate using Multiple Deployments

Controlled testing of new versions in production

- Assume an application running as a Deployment, exposed as a Service
- To apply a new application version in production, a second Deployment can be used using labels in common with the first Deployment
 - Canary deployment allows for limited testing of new version in production
 - Blue/green deployment

Strategic Approach: Canary Deployment

Controlled testing of the update on production

- Consider a Service selecting pods from a Deployment of application pods
- In a canary deployment, a second Deployment (Canary Deployment) is created with pods for the new version, with labels matching the Service's selector
- Service directs some requests to pods on the Canary, allowing testing of changes in production
- If a malfunction is detected, it will only impact a small portion of the Pods and can be undone.

Strategic Approach: Canary Deployment

DEPLOYMENT 1

image: tomcat
replicas: 3
type=webserver
channel=**production**

POD 1 – Replica 1
tomcat

POD 1 – Replica 2
tomcat

POD 1 – Replica 3
tomcat

SERVICE

selector:
type=webserver

DEPLOYMENT 2

image: tomcat:8.5.5
replicas: 1
type=webserver
channel=**canary**

POD 1 – Replica 1
tomcat:8.5.5

Strategic Approach: Canary Deployment

Decisions after running the canary Deployment in production

- If the application error rate is not increasing and Canary Deployment is stable:
 - The main Deployment can be updated to the newer version (using Rolling Update for example) and then the Canary can be discarded; OR
 - The Canary can be scaled up and reconfigured and the old Deployment can be discarded.
- If the test results in failure, the Canary deployment can be deleted

Strategic Approach: Blue/Green Deployment

Complete environment switch from one version to another

- With a Blue/Green deployment, you create a new full-scale Deployment in addition to the current production Deployment
- Reconfiguring the pod label selector on the application's Service allows choice of directing requests to old Deployment or new Deployment
- Similar to effect of Replace strategy without application downtime

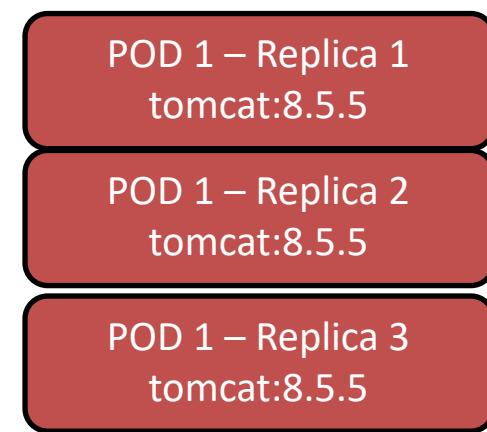

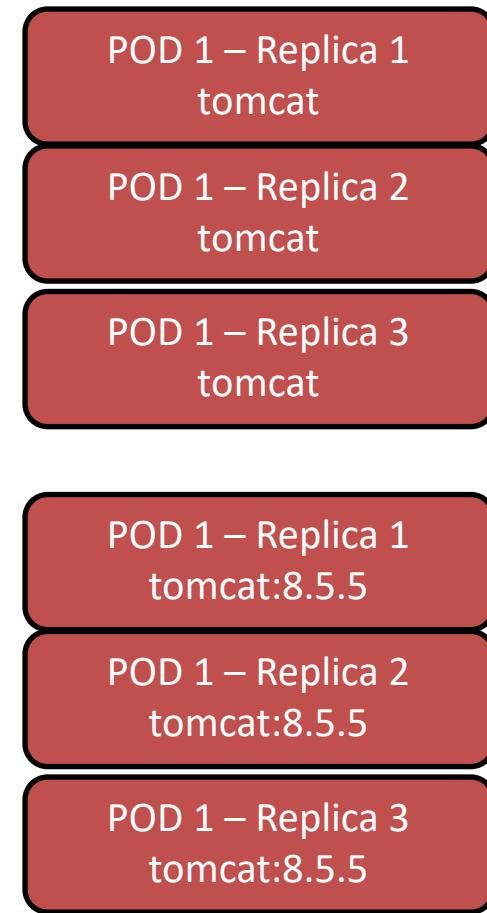

Strategic Approach: Blue/Green Deployment

DEPLOYMENT 1

```
image: tomcat
replicas: 3
type=webserver
color=blue
```

DEPLOYMENT 2

```
image: tomcat:8.5.5
replicas: 1
type=webserver
color=green
```

SERVICE

```
selector:  
type: webserver  
color=blue
```

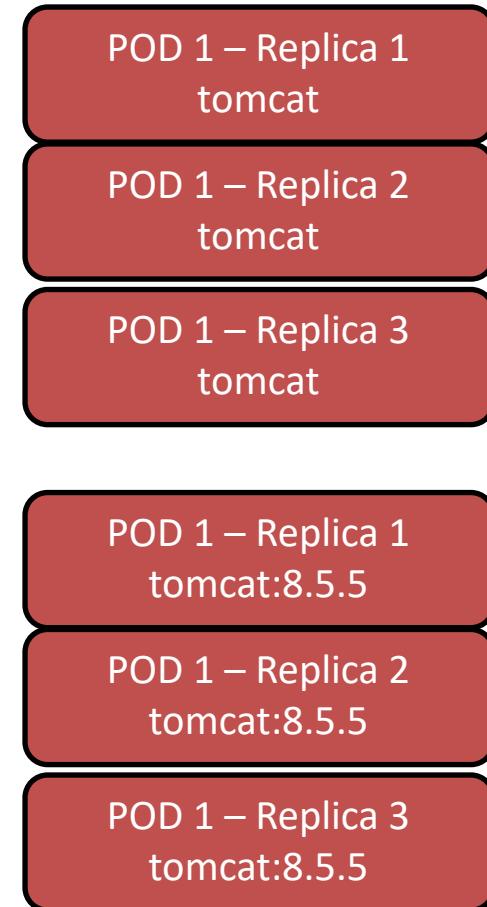

Strategic Approach: Blue/Green Deployment

DEPLOYMENT 1

```
image: tomcat  
replicas: 3  
type: webserver  
color=blue
```

DEPLOYMENT 2

```
image: tomcat:8.5.5  
replicas: 3  
type: webserver  
color=green
```

SERVICE

```
selector:  
type: webserver  
color:green
```

Persistent Volumes

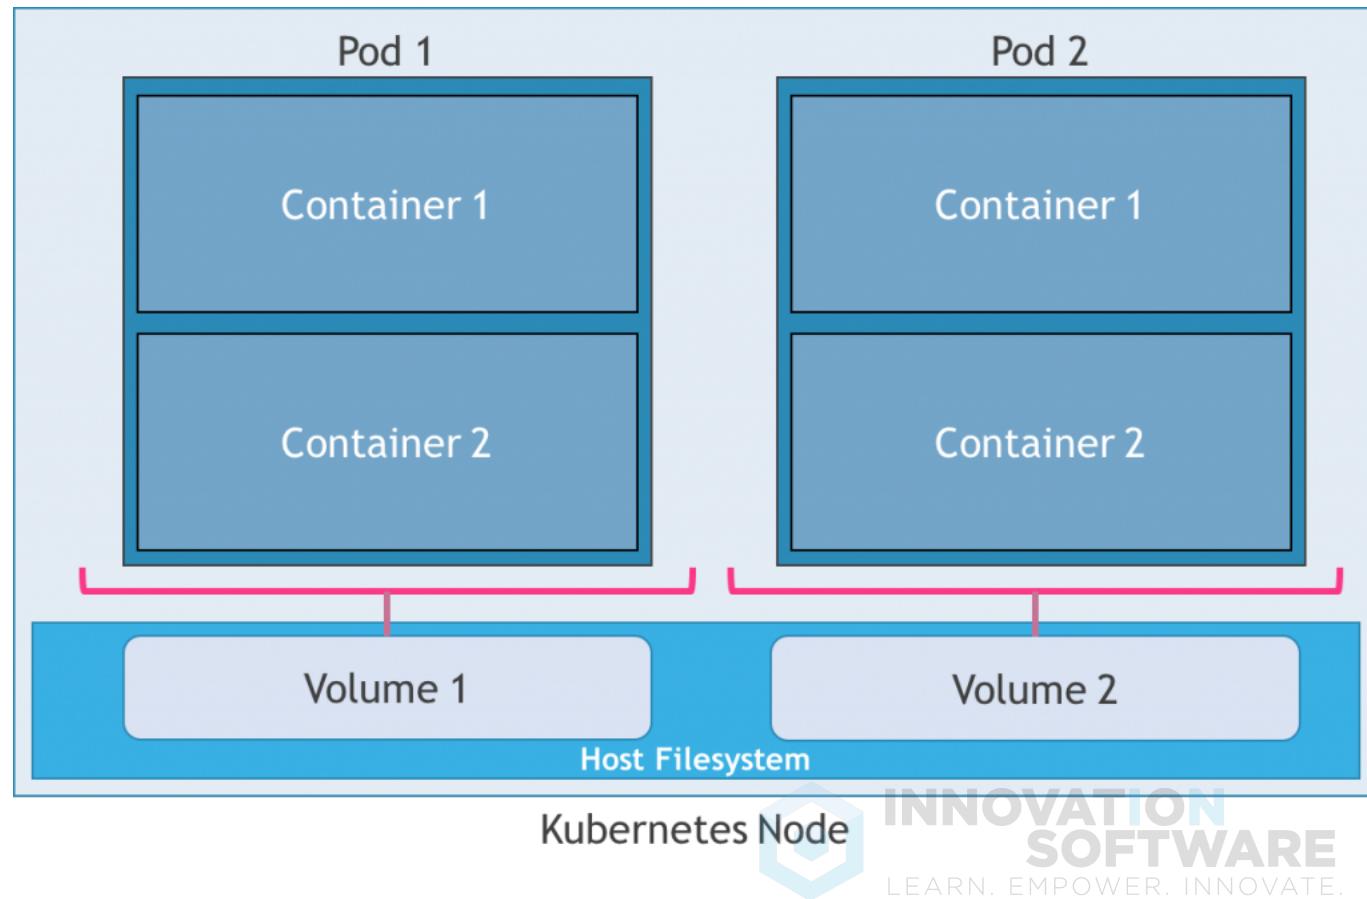

Host Based Storage

- Containers in a Pod share the same volume
- Host based storage
 - Local filesystem
- Removed when Pod is deleted
- Types of local storage
 - emptyDir
 - hostPath

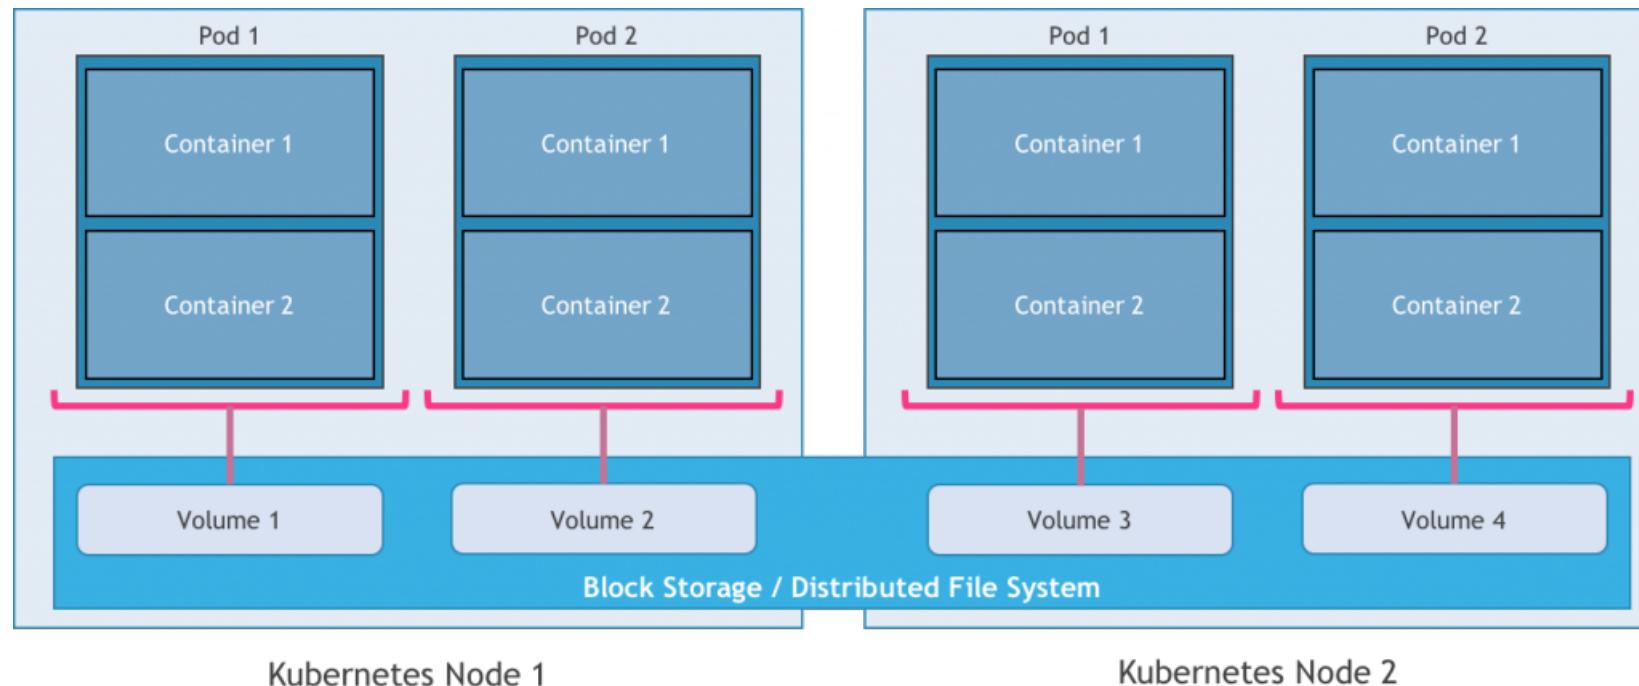

Host Based Storage

- Common use cases
 - Scratch disk
 - Store temp config data
- hostPath
 - Directories on host
 - Owned by root

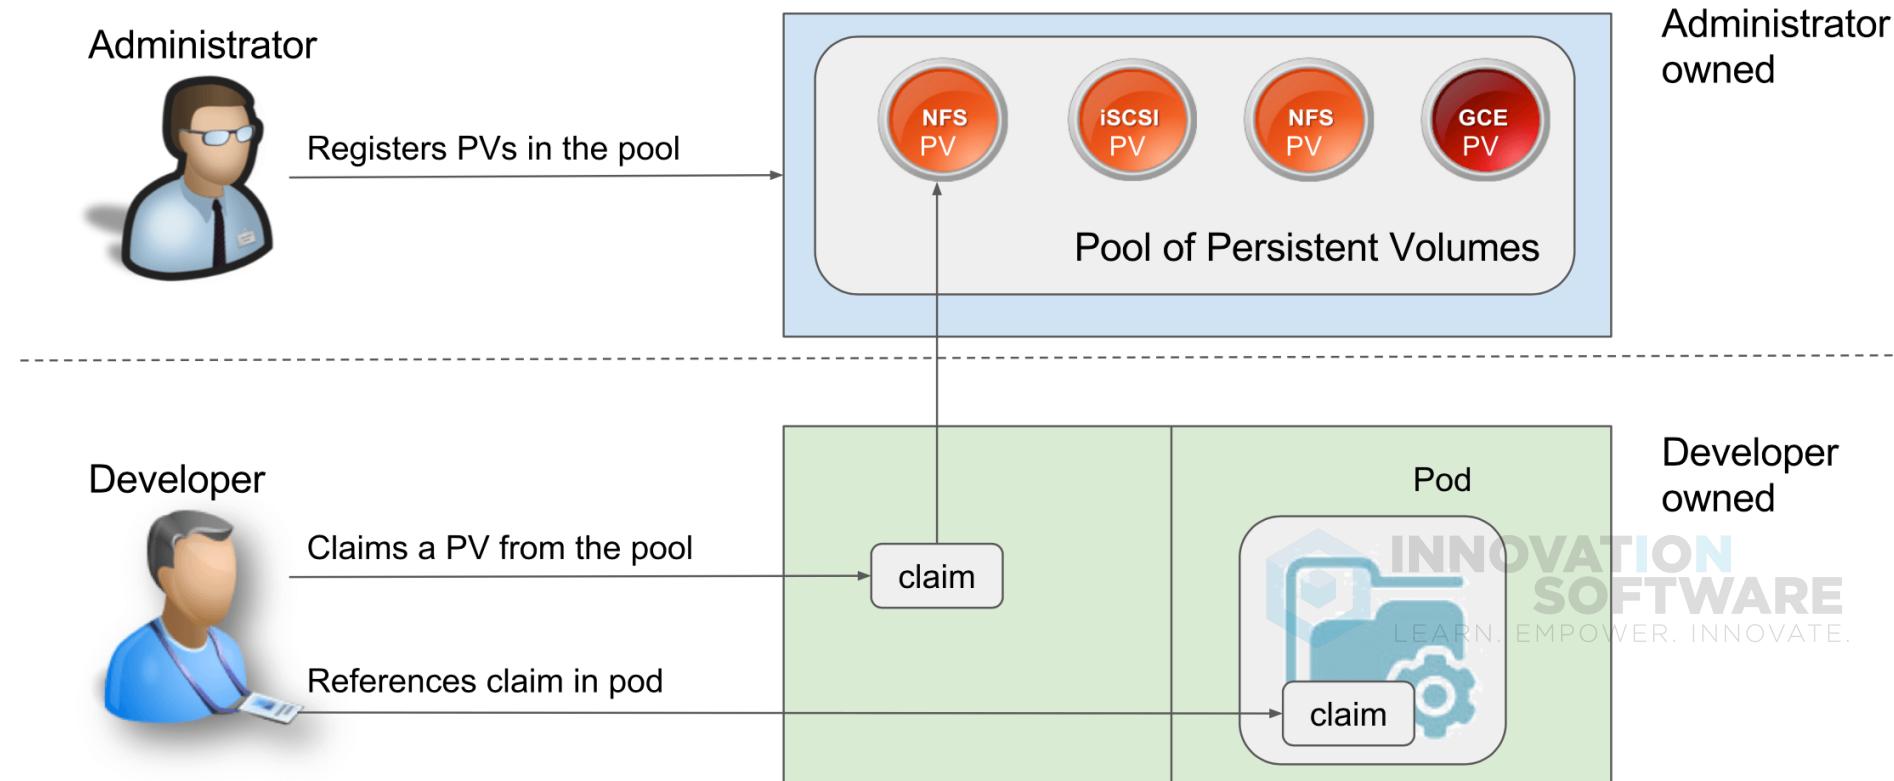

Non-Host Based Storage

- Common use cases
 - Persistent data
 - DB, Stateful apps
- EBS
- GCE Persistent Disks
- NFS, NetApp, GlusterFS

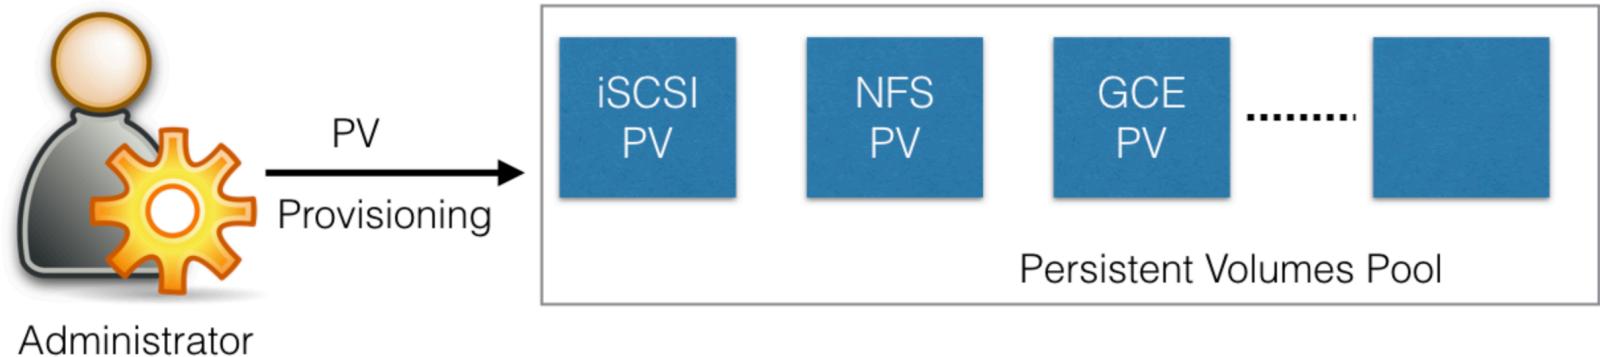

Persistent Volumes & Claims

- Operations creates PVs
 - Real storage details
 - Storage “LUN”
- Devs claim a PV
 - Self-service
 - Flexibility
 - Speed

Persistent Volumes

- Admin managed
- Quotas
- Access control
- Storage pools

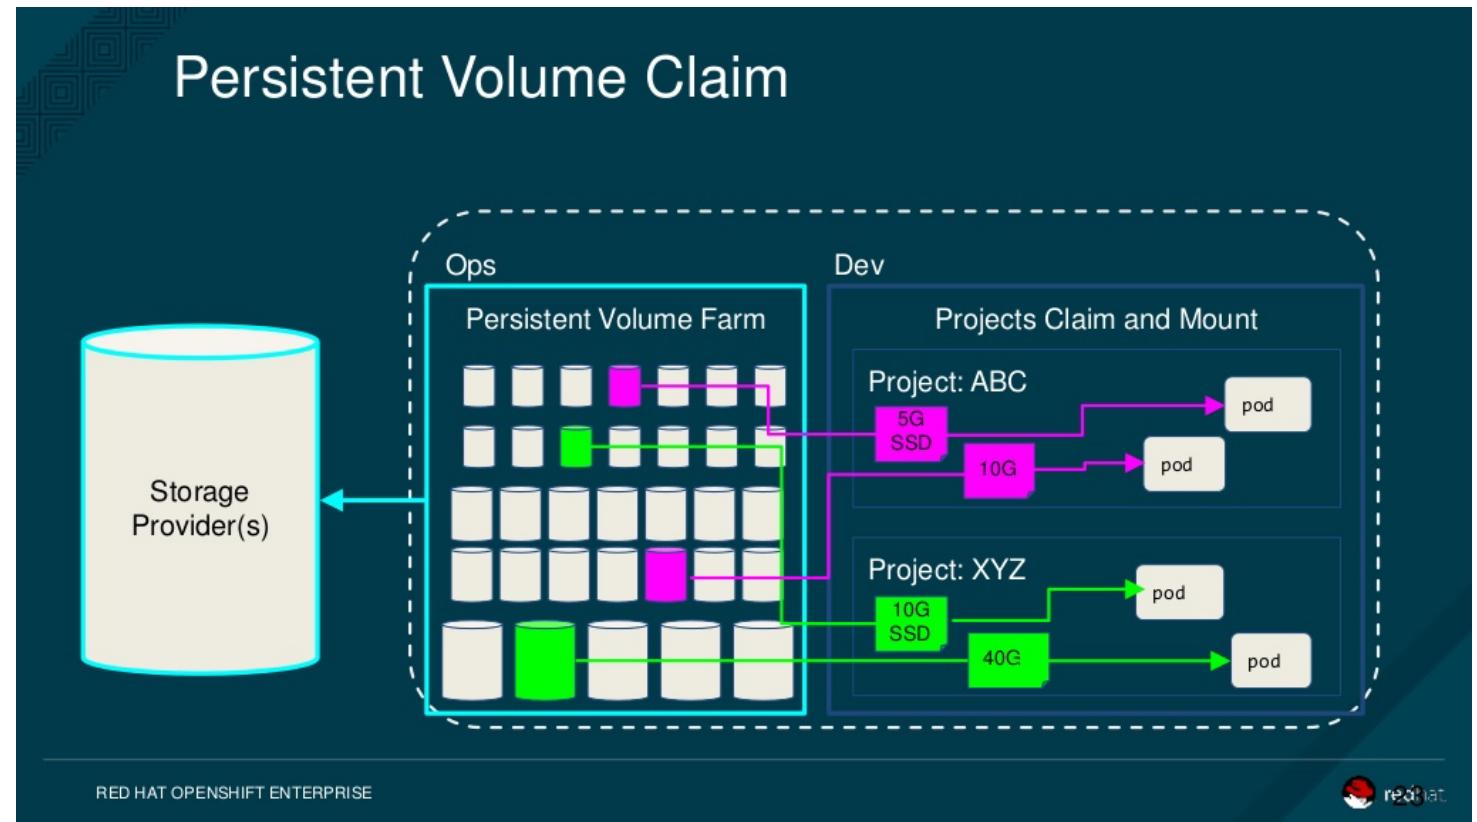

Persistent Volumes

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: pv-aws
spec:
  capacity:
    storage: 12Gi
  accessModes:
    - ReadWriteOnce
  persistentVolumeReclaimPolicy: Recycle
  storageClassName: slow
  awsElasticBlockStore:
    fsType: "ext4"
    volumeID: "vol-f37a03aa"
```

Persistent Volume Claims

- Allows Devs to claim storage without worrying about management.
- Devs only see storage assigned to projects they are in.

Persistent Volume Claims

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: mongodb-pv-claim
  labels:
    app: mongodb
spec:
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 10Gi
```

```
apiVersion: extensions/v1beta1
kind: Deployment
metadata:
  name: rsvp-db
spec:
  replicas: 1
  template:
    metadata:
      labels:
        appdb: rsvpdbs
    spec:
      containers:
        - name: rsvpd-db
          image: mongo:3.3
          ports:
            - containerPort: 27017
          volumeMounts:
            - name: mongodb-persistent-storage
              mountPath: /data/db
          volumes:
            - name: mongodb-persistent-storage
              persistentVolumeClaim:
                claimName: mongodb-pv-claim
```

ConfigMap

KEY VALUES

ConfigMap

ConfigMap

- Many applications require configuration via:
 - Config Files
 - Command-Line Arguments
 - Environment Variables
- These need to be decoupled from images to keep portable
- ConfigMap API provides mechanisms to inject containers with configuration data
- Store individual properties or entire config files/JSON blobs
- Key-Value Pairs

ConfigMap

- Not meant for sensitive information
- PODs or controllers can use ConfigMaps

1. Populate the value of environment variables
2. Set command-line arguments in a container
3. Populate config files in a volume

```
kind: ConfigMap
apiVersion: v1
metadata:
  creationTimestamp: 2016-02-18T19:14:38Z
  name: example-config
  namespace: default
data:
  example.property.1: hello
  example.property.2: world
  example.property.file: |-  
    property.1=value-1  
    property.2=value-2  
    property.3=value-3
```

ConfigMap from directory

- 2 files in docs/user-guide/configmap/kubectl
 - game.properties
 - ui.properties

game.properties

```
enemies=aliens
lives=3
enemies.cheat=true
enemies.cheat.level=noGoodRotten
secret.code.passphrase=UUDDLRLRBABAS
secret.code.allowed=true
secret.code.lives=30
```

ui.properties

```
color.good=purple
color.bad=yellow
allow.textmode=true
how.nice.to.look=fairlyNice
```

ConfigMap from directory

```
kubectl create configmap game-config --from-file=docs/user-guide/configmap/kubectl
```

```
kubectl describe configmaps game-config
```

```
Name: game-config  
Namespace: default  
Labels: <none>  
Annotations: <none>
```

```
Data
```

```
====
```

```
game.properties: 121 bytes  
ui.properties: 83 bytes
```

ConfigMap from directory

```
kubectl get configmaps game-config -o yaml
```

```
apiVersion: v1
data:
  game.properties: |-  
    enemies=aliens  
    lives=3  
    ...  
  ui.properties: |-  
    color.good=purple  
    ...  
kind: ConfigMap
metadata:
  creationTimestamp: 2016-02-18T18:34:05Z
  name: game-config
  namespace: default
  resourceVersion: "407"-  
  selfLink: /api/v1/namespaces/default/configmaps/game-config
  uid: 30944725-d66e-11e5-8cd0-68f728db1985
```

ConfigMap from files

```
kubectl get configmaps \  
game-config-2 \  
-o yaml
```

```
kubectl create configmap \  
game-config-2 \  
--from-file=file1 \  
--from-file=file2
```

```
apiVersion: v1  
data:  
  game.properties: |-  
    enemies=aliens  
    lives=3  
    ...  
  ui.properties: |-  
    color.good=purple  
    ...  
kind: ConfigMap  
metadata:  
  creationTimestamp: 2016-02-18T18:52:05Z  
  name: game-config-2  
  namespace: default  
  resourceVersion: "516"-  
  selfLink: /api/v1/namespaces/default/configmaps/game-config-2  
  uid: b4952dc3-d670-11e5-8cd0-68f728db1985
```

ConfigMap options

--from-file=/path/to/directory

--from-file=/path/to/file1 (/path/to/file2)

Literal key=value: --from-literal=special.how=very

ConfigMap in PODs

- Populate Environment Variables

```
apiVersion: v1
kind: ConfigMap
metadata:
  name: special-config
  namespace: default
data:
  special.how: very
  special.type: charm
```

OUTPUT

```
SPECIAL_LEVEL_KEY=very
SPECIAL_TYPE_KEY=charm
```

```
apiVersion: v1
kind: Pod
metadata:
  name: dapi-test-pod
spec:
  containers:
    - name: test-container
      image: busybox
      command: ["/bin/sh", "-c", "env"]
      env:
        - name: SPECIAL_LEVEL_KEY
          valueFrom:
            configMapKeyRef:
              name: special-config
              key: special.how
  restartPolicy: Never
```

ConfigMap Restrictions

- ConfigMaps must be created before they are consumed
- ConfigMaps can only be referenced by objects in the same namespace
- Quota for ConfigMap size not implemented yet
- Can only use ConfigMap for PODs created through API server.

Secrets

Application Secrets

What secrets do applications have?

- Database credentials
- API credentials & endpoints (Twitter, Facebook etc.)
- Infrastructure API credentials (Google, Azure, AWS)
- Private keys (TLS, SSH)
- Many more!

Application Secrets

It is a bad idea to include these secrets in your code.

- Accidentally push up to GitHub with your code
- Push into your file storage and forget about
- Etc.

Application Secrets

There are bots crawling GitHub searching for secrets

Real life example:

Dev put keys out on GitHub, woke up next morning with a ton of emails and missed calls from Amazon

- 140 instances running under Dev's account.
- \$2,375 worth of Bitcoin mining

Create Secret

- Designed to hold all kinds of sensitive information
- Can be used by Pods (filesystem & environment variables) and the underlying kubelet when pulling images

```
apiVersion: v1
kind: Secret
metadata:
  name: mysecret
type: Opaque
data:
  password: mmyWfoidfluL==
  username: NyhdOKwB
```

Pod Secret

```
kind: Pod
metadata:
  name: secret-env-pod
spec:
  containers:
    - name: mycontainer
      image: redis
      env:
        - name: SECRET_USERNAME
          valueFrom:
            secretKeyRef:
              name: mysecret
              key: username
```

Volume Secret

```
spec:  
  containers  
    - name: mycontainer  
      image: redis  
      volumeMounts:  
        - name: "secrets"  
          mountPath: "/etc/my-secrets"  
          readOnly: true  
  volumes:  
    - name: "secrets"  
      secret:  
        secretName: "mysecret"
```

Labs: ConfigMap & Secrets

Role Based Access Controls

RBAC

- Considered stable in Kubernetes 1.8 and later
- To enable start apiserver with
 - `--authorization-mode=RBAC`
 - This allows for more fine-grained control of access permissions

RBAC Roles

- Role used to grant access to resources in a single namespace

```
kind: Role
apiVersion: rbac.authorization.k8s.io/v1
metadata:
  namespace: default
  name: pod-reader
rules:
- apiGroups: [""] # "" indicates the core API group
  resources: ["pods"]
  verbs: ["get", "watch", "list"]
```

RBAC ClusterRole

- ClusterRole used to grant access to resources that are cluster specific, not namespace specific

```
kind: ClusterRole
apiVersion: rbac.authorization.k8s.io/v1
metadata:
  # "namespace" omitted since ClusterRoles are not namespaced
  name: secret-reader
rules:
- apiGroups: []
  resources: ["secrets"]
  verbs: ["get", "watch", "list"]
```

RBAC RoleBinding

- Grant permissions defined in a role to user or set of users

```
# This role binding allows "jane" to read pods in the "default" namespace.
```

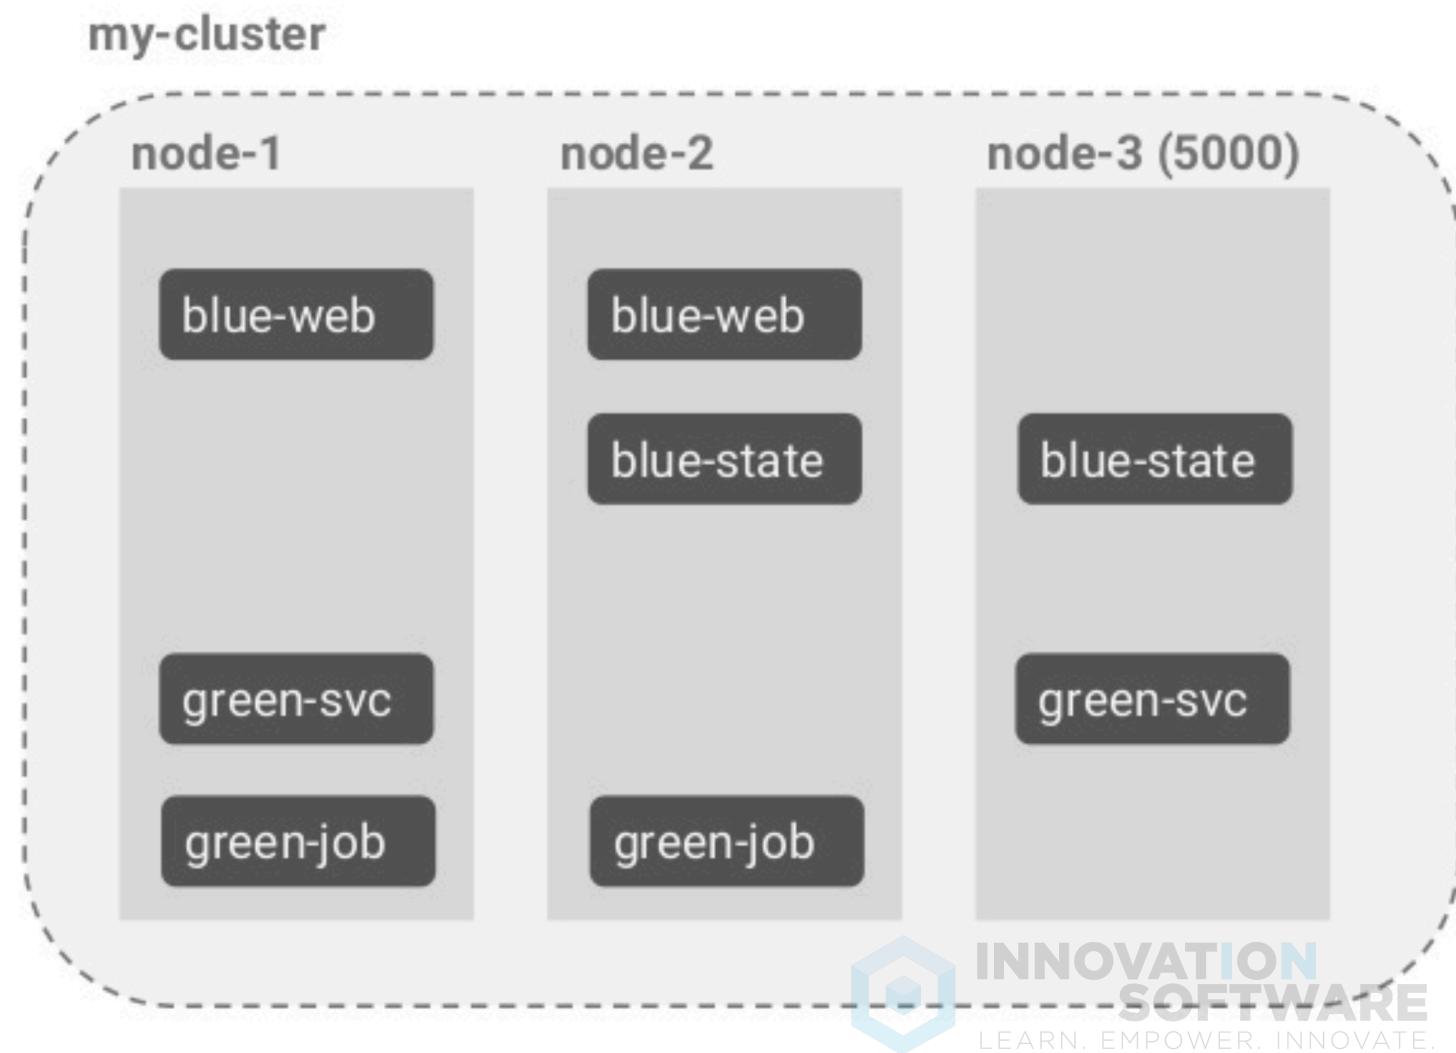

```
kind: RoleBinding
apiVersion: rbac.authorization.k8s.io/v1
metadata:
  name: read-pods
  namespace: default
subjects:
- kind: User
  name: jane
  apiGroup: rbac.authorization.k8s.io
roleRef:
  kind: Role
  name: pod-reader
  apiGroup: rbac.authorization.k8s.io
```

Without fine-grained Access:

- Authorization at cluster level
- All pods have same authorization

Without controlled scheduling:

- Lack flexibility for multi-workload

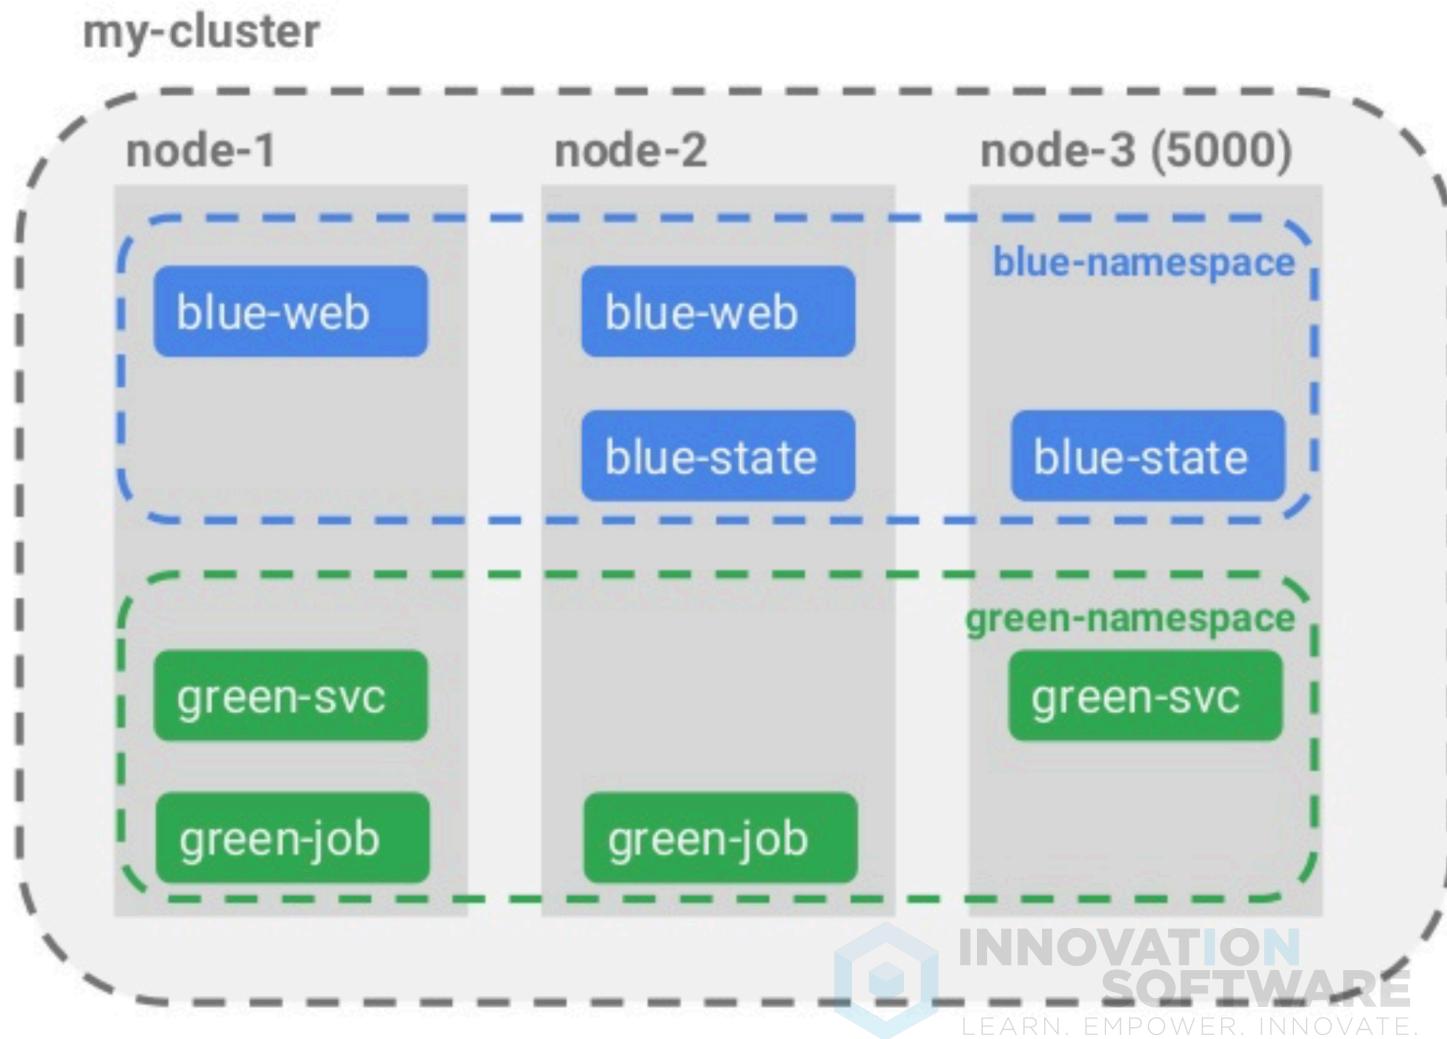

Introducing RBAC:

- Per-namespace/ resource, role, action

Examples:

- **Alice** can list **Eng** services, but not **HR**
- **Bob** can create Pods in **Test** namespace, but not in **Prod**
- **Scheduler** can read **Pods** but not **Secrets**

RBAC lab

- Create user
- Generate SSL credentials for new user
- Create RBAC Role and RoleBinding
- Assign correct permissions to user
- Confirm RBAC is working as expected

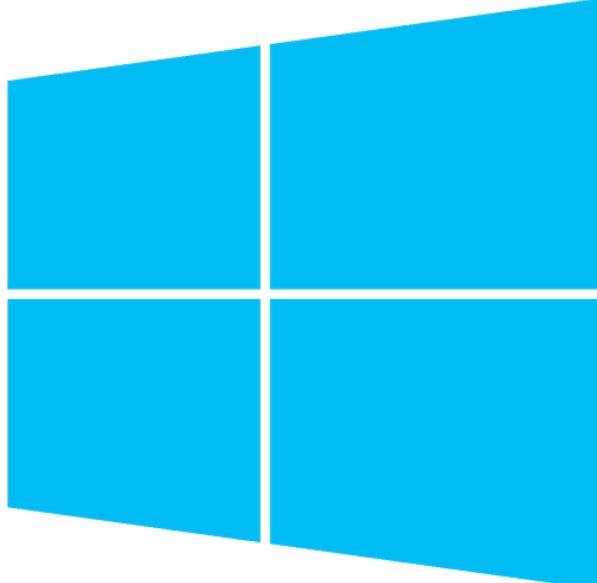

Run Kubernetes locally - Minikube

Minikube: Run Kubernetes All-In-One

Run single-node Kubernetes cluster on local machine

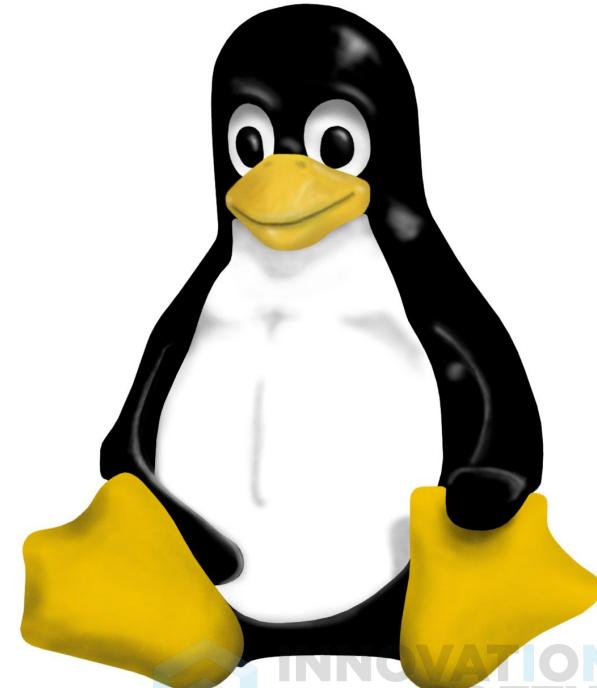

- Minikube runs on all 3 operating systems
 - Windows, Mac, and Linux

- VirtualBox
- Hyper-V

- VirtualBox
- Xhyve
- Vmware Fusion

- VirtualBox
- KVM
